INDEX. REMOTE STORAGE

[For Alphabetical List of Subjects, except Patents, see GENERAL INDEX on p. xv.]

Editorial Notes—Gas, Lighting, &c.

Accounts, Gas, The Monthly Collection of, 106
 Accounts of Gas Companies, Mr. A. Lass on the, 1017
 America, Mr. H. E. Jones on Electric Lighting and Oil Gas Processes in, 626
 Armitage, Mr. C., and the Management of the Lancaster Corporation Gas Works, 368
 Average Meter System, A Condemnation of the, 106
 Ball, Mr. T. B., Attack by Mr. G. Bray on, 239
 Bennett, Mr. W. H., Resignation by, of the Secretaryship of The Gas Institute, 1102
 Bills and Provisional Orders (Session 1889), Notices of Applications for, 974
 Birmingham Corporation Gas Undertaking, 282, 1018
 Bramwell's, Sir F., Address at the British Association Meeting, 453
 Bray, Mr. G.—
 Attack on Mr. G. Livesey, 325
 Attack on Mr. T. B. Ball, 239
 Attempted Expulsion of, from The Gas Institute, 105
 Bristol Gas Company and the Sliding Scale, 755
 British Association for the Advancement of Science—Annual Meeting at Bath, 326, 453, 497
 Bury, Encouraging Small Gas Consumers at, 670
 Carr, Mr. W., and the Halifax Corporation Gas Coal Contracts, 454, 498, 627, 928, 1102
 Carshalton, Proceedings in Regard to a Leakage of Gas at, 880
 Chaney's, Mr. H. J., Report on the Work of the Standards Department of the Board of Trade, 879
 Christmas Time, Gas Works at, 1101
 Churchill's, Lord R., Commission Bill, 155
 Circular Inquiry Nuisance, 10, 107, 1103
 Coal and Wine Dues, The Proposed Continuance of the, 59, 839
 Coal Owners, Miners, and Agents, The Position of, 711, 754, 794
 Coke, The Demand for, 10, 197
 Commercial Gas Company, The Half Year's Working of the, 582, 626
 Commission Question, 155, 880
 Consumers of Gas, How to Secure the Small, 670, 713, 838
 County Council for London, The Forthcoming, 753, 1102
 County Government Bill, 154
 Cowpen, A Demonstration against Darkness at, 540
 Dalgliesh's, Mr. J., Paper on the Effect of Oil and Other Illuminants on Gas Consumption, Discussion of, 1062
 Dinsmore Gas Process, 794
 District Associations of Gas Managers, The Value of, 539, 670
 Dublin, Gas Affairs in, 1063
 Eastern Counties Gas Managers' Association, 582
 Examinations in Gas Manufacture, The Last, 409
 Fog and Smoke, The Difficulty of Dealing with, 793, 927
 Fox, Mr. T. K., and the Halifax Corporation Gas Coal Contracts, 454, 498, 627, 755
 Gadd's, Mr., Spiral Guide Framing for Gasholders, 410
 Gas Burners, A Discussion on, at the North British Association Meeting, 325
 Gas Consumers, How to Secure the Small, 670, 713, 838
 Gas Engineers, The Pay and Position of, 10, 1018
 Gas Institute—
 Annual Meeting—Comments on the Papers, 9
 Bray, Mr., and The, 105
 Position of The, 153, 455, 1061
 Resignations of Officers, 238, 1102
 Transactions for 1888, 837

Gas Lighting and Public Security, 625
 Gas Making, Mr. W. Thomson on, 928
 Gas Manufacture, Mr. L. T. Wright's Lectures on, 196
 Gas Manufacture, The Last Examinations in, 409
 Gas Scandals, Effect of, upon Gas Engineers and Managers, 626
 Gas Supply, Mr. J. M'Gilchrist on, 281
 Gas Testing Popularized in Paris, 671
 Gas Works Officials at Birmingham and Elsewhere, The Emoluments and Responsibilities of, 1018
 Gasholder Extension, Mr. J. Wright on, 670
 Gasholder Guide Framing Question, The, 195, 326, 410, 795, 838, 929
 Gaslight and Coke Company—
 Consumers and their Contracts—A Hard Case, 410
 Directors' Report and Accounts, 237
 Half Yearly Meeting, 282
 Reduction in Price, 794
 Halifax Corporation Gas Coal Contracts, Serious Charges in Connection with the, 59, 454, 498, 583, 627, 755, 838, 928, 1102
 Humphrys, Mr. N. H., on District Associations of Gas Managers, 670
 Hunter, Mr. S., Conviction of, for Perjury and Forgery, 58
 Inquiry Circular Nuisance, 10, 107, 1103
 Inventions, The Importance of Little, 541
 Jones, Mr. H. E., on Electric Lighting and Oil Gas Processes in America, 626
 Lancaster Corporation Gas Works, Mr. C. Armitage's Management of the, 368
 Lass, Mr. A., on Gas Companies' Accounts, 1017
 Lawrence Automatic Gas Company Again, 974
 Leakage of Gas at Carshalton, Proceedings in Regard to a, 880
 Lever, Mr. Ellis, and His Charges in Connection with Gas Coal Contracts, 754, 838, 928
 Lewis, Mr. J. T., on the Competition of Petroleum with Gas, 712
 Libel upon Mr. W. J. Warner, 155
 Light Standards, The Question of, 497
 Liverpool United Gas Company, The Affairs of the, 368
 Livesey, Mr. G.—
 Bray, Mr. G., and, 325
 Gasholder Guide Framing, 838
 Resignation from The Gas Institute, 238
 Local Government (England and Wales) Act, 367
 London County Council, The Forthcoming, 753, 1102
 M'Gilchrist, Mr. J., on Gas Supply, 281
 Manchester and its Neighbours, 154
 Manchester Corporation Gas Department, The Affairs of the, 196
 Manchester District Institution of Gas Engineers, Meetings of the, 410, 1062
 Meter, Mr. Price's Prepayment, 839
 Method, The Importance of, in Stating Working Results, 499
 Metropolitan Board of Works and the London Coal and Wine Dues, 839
 Midland Association of Gas Managers, Meeting of the, 712
 Montreal Gas Works, Destruction of a Gasholder at the, 57
 Mooney, Mr. W., on the Gasholder Guide Framing Question, 929
 Nelson Local Board Gas Undertaking, Limitation of the Profits of the, 411
 Newbigging, Mr. T., on Mr. Gadd's System of Guiding Gasholders, 410
 North British Association of Gas Managers, The Meeting of the, 196, 281, 325
 North of England Gas Managers' Association, Meeting of the, 670
 Oil and other Illuminants, Effect of, on Gas Consumption—Discussion of Mr. J. Dalgliesh's Paper, 1062
 Oil Gas Fuel Schemes, 581
 Ornament in Engineering Work, 973
 Paris Municipality and Gas Testing, 671
 Parliamentary Notices for the Session of 1889, 974
 Petroleum Explosions, 712
 Petroleum, The Competition of, with Gas—Mr. Lewis's Paper at the Midland Association, 712

Price, Mr. W. E., on Extending the Use of Gas, 838
 Private Bill Legislation, The Report of the Joint Committee on, 155
 Profits, Gas, of the Nelson Local Board, Limitation of the, 411
 Public Security, Gas Lighting and, 625
 Rochdale Corporation Gas Engineer, Mr. G. Bray and the, 239
 Rochdale, Effect of "Gas Scandals" on Public Opinion at, 626
 Rotherhithe, An Experiment in Dispensing with Gasholder Guide Framing at, 195, 326
 Russell, The Hon. F. A. Rollo, on Smoke and Fog, 927
 Sliding Scale, The Bristol Gas Company and the, 755
 Smoke and Fog, The Difficulty of Dealing with, 793, 927
 Somerville, Mr. James, on Gasholder Guiding, 795
 South Metropolitan Gas Company—
 Bray, Mr. G., and the, 325
 Directors' Report and Accounts, 238
 Half Yearly Meeting, 325
 Rotherhithe Gasholder Experiment, 195, 326
 Southern District Association of Gas Engineers and Managers, The Meeting of the, 838
 Standards Department of the Board of Trade, The Report of the, 879
 Standards of Light, The Question of, 497
 Stokers, Gas, Holidays for, 282
 Strachan, Mr. G. R., on the Average Meter System, 106
 Street Lighting, Improved, in London, 1018
 Strike in the Coal Trade, 711, 754, 794
 Swansea Gas Company and the Corporation, 369, 627
 Sydney Gas Works, The Drawings of Messrs. C. and W. Walker's New Holder for the, 974
 Thomson, Mr. W., on Gas Making, 928
 Walker's, Messrs. C. and W., New Holder for the Sydney Gas Works, The Drawings of, 974
 Warner, Mr. W. J., Libel upon, 155
 Water Gas Auxiliary to Coal Gas, 669
 Water Gas, Mr. W. L. Wildy on, 1019
 Weights and Measures Act, 1878, The Proceedings of the Board of Trade under the, 879
 Wolverhampton, The Lighting of, 498
 Woodall, Mr. H., Resignation by, of the Presidency of The Gas Institute, 1102
 Working Results, The Importance of Method in Stating, 499
 Wright, Mr. J., on Gasholder Extension, 670
 Wright's, Mr. L. T., Lectures on Gas Manufacture, 196
 Wrigley, Mr. E. G., and the Halifax Corporation Gas Coal Contracts, 627, 755, 838

Water and Sanitary Affairs.

Accounts of the London Water Companies, Mr. A. Lass's Analysis of the, 583
 Air and Water, Dr. P. F. Frankland on Micro-Organisms in, 107
 Bacteriological Character of the London Water Supply in 1887, Dr. P. F. Frankland on the, 239
 Bills, Water, The Proposed Applications for (Session 1889), 975
 Bramwell, Lord, on the London Water Companies, 1063
 Bramwell, Sir F., on the Water Supply of Towns, 455
 Burnley, Dispute as to the Recovery of Overpaid Water Rates at, 11
 Chelsea Water Company—
 Cutting Off a Consumer's Supply, 541
 Half Yearly Meeting, 1064
 Churchill, Lord Randolph, on the Need of Sanitary Legislation, 929

Colquhoun, Sir P., on the Contamination of the Thames by the Weybridge Sewage Treatment Process, 839
 Constant Supply in the Metropolis, The Question of, 327, 541
 Cutting Off Water, Water Companies and their Powers in Regard to, 541
 Denton, Mr. Bailey, on the Replenishment of Underground Waters, 455
 Dobbs, Mr. A., on the New River Company's Charges, 756
 Ealing, Opening of a New Water Reservoir at, 239
 East London Water Company—
 Dispute with a Consumer under Mr. Forrest Fulton's Act, 11
 Half Yearly Meeting, 628
 Frankland, Dr. P. F., on Micro-Organisms in Air and Water, 107, 239
 Grand Junction Water Company—
 Half Yearly Meeting, 1064
 New Reservoir at Ealing, 239
 Scott, General, on the Rejected Bill of the, for Additional Powers, 819
 Lass's, Mr. A., Analysis of the London Water Companies' Accounts, 583
 Legislation, Proposed, in regard to Water Supply (Session 1889), 975
 Local Government Board, The Annual Report of the, 839
 London Water Companies, The Contributions by the, to the Revenues of the Thames Conservators, 327
 London Water Supply—
 Frankland, Dr. P. F., on the Bacteriological Character of the, in 1887, 239
 Proposal to Poison the, 839, 881
 Scott, General, on the Future of the, 810
 Manchester, Important Sewage Scheme for, 542
 Metropolitan Board of Works, The Sewage Disposal Scheme of the, 369
 Micro-Organisms in Air and Water, Dr. P. F. Frankland on, 107, 239
 New River Company and their Charges—A Protest from Mr. A. Dobbs, 756
 Oxford Water Works Engineers, A Commission Dispute between the, 197
 Paris, M. Ritter's Proposed Scheme of Water Supply for, from Switzerland, 369
 Parliament, Notices of Applications to (Session 1889), 975
 Rawlinson, Sir R., on the Sewage Disposal Scheme of the Metropolitan Board of Works, 369
 Ritter's, M., Proposed Scheme of Water Supply for Paris from Switzerland, 369
 Sewage, The Pollution of the Thames by, 327, 369, 795, 839, 881, 929, 1063
 Southwark and Vauxhall Water Company—
 Charge against a Consumer of Unlawfully Using Water, 156
 Half Yearly Meeting, 1064
 Streatham Well—An Interesting Geological Problem, 795
 Staines Local Board and the Sewage Pollution of the Thames, 795
 Thames Conservancy Acts, Necessity for the Amendment of the, 831, 1063
 Thames Conservators, The Metropolitan Water Companies and the Revenues of the, 327
 Thames, The Sewage Pollution of the, 327, 369, 795, 839, 881, 929, 1063
 Theft of Water, What Constitutes a, 156
 Towns, Sir F. Bramwell on the Water Supply of, 455
 Underground Waters, Mr. Bailey Denton on the Replenishment of, 455
 Unlawful Use of Water—Charge against a Consumer of the Southwark and Vauxhall Water Company, 156
 Water and Air, Dr. P. F. Frankland on Micro-Organisms in, 107, 239
 Water Companies' (Regulation of Powers) Act, The Working of the, 11
 Water Engineers, Resident and Consulting—A Commission Dispute at Oxford, 197
 Water Rates—
 Consumers and their Liabilities for, 11
 Recovery of Overpaid—The Burnley Case, 11
 Weybridge, The Sewage Treatment Process at, and the Pollution of the Thames, 839, 881

Essays, Commentaries, and Reviews.

Acts, Gas and Water, for 1888, 757, 842, 884
 Albion Engine Company's Catalogue, 1066
 Alkali Act, Annual Report of the Chief Inspector (Mr. A. E. Fletcher) under the, 22
 Artificial Lighting, The Future of, 585
 Australian Gaslight Company, Description of a New Three-Lift Holder for the, 977, 1021, 1066, 1105
 Bray's, Mr. G., Attacks upon Members of The Gas Institute, 242
 Brussels Exhibition, Gas Appliances at the, 159
 Central Station Electric Lighting, 975

Coke, The Demand for, 157
 Defries, Mr., on Oil and Gas as Illuminants, 1020
 Dibdin, Mr. W. J., on Standards of Light, 1105
 Divination, Finding Water by, 544, 630, 1022
 Ealing, A New Storage Reservoir at, 241
 Edinburgh and Leith Gas Works Transfer, 21
 Electric Lighting Memoranda—
 Adelphi Theatre, Lighting of the, 198
 America, Mr. H. E. Jones on Electric Lighting and Gas in, 628
 Anglo-American Brush Company, 672
 Arc Lamps in Canada, The Cost of, 797
 Artificial Lighting, Effect of, on Water Colours, 284
 Australia, Electric Lighting in, 882
 Ayrton, Professor, on the Electrical Transmission of Power, 499
 Barnet Electric Lighting Experiment, 115, 456, 500, 628
 Birmingham Electric Lighting Scheme, 543, 841
 Board of Trade Report under the Electric Lighting Act, 115
 Boston Edison Company, The, 65
 Bradford Corporation Experiment, 115, 796
 British Association Meeting, Electric Lighting at the, 323, 456
 Canada, Cost of Arc Lighting in, 797
 Carbons, The Consumption of Arc Lamp, 672
 Charges, Proposed, for Electric Lighting at Bradford, 115
 Chelsea Electricity Supply Company, 241
 Cost of Electric Lighting, 412, 456, 797, 682, 976
 Cost of Small Electric Lighting Installations, 882
 Crompton and Co., Messrs. R. E., 841, 1020
 Dublin, Gas and Electric Light in, 756
 Edison and Brush Lawsuit, Judgment in the, 156, 198
 Edison and Swan Electric Light Company, 757, 796
 Efficiency, The Maximum, of Electric Lamps, 65
 Electrical and Allied Trades Section of the London Chamber of Commerce, Proposed, 241
 Electrical Review—
 Gas Directors and Electric Lighting, 840
 The Manager of the Metropolitan Electric Supply Company and the, 714
 Electrical Speculation, Prospective Revival in, 198
 Electric Lighting Act Amendment Bill, 19
 Electricity v. Gas, Mr. John Stent on, 500
 Exeter, The Proposed Electric Lighting of, 757
 Failures of Electric Lighting, 976
 Faure Accumulator Company, The, 882
 Forbes, Professor G., on the Westinghouse System, 543
 Gas Directors and Electric Lighting, 840
 Gaulard and Gibbs Patents, The, 114
 German Estimate, A, of the Cost of Electric Lighting, 412
 Glasgow Post Office, Failure of the Electric Light at the, 976
 Gramme, M., Award of the Volta Prize to, 671
 Grosvenor Gallery Company, The, 65, 882
 Gülcher Electric Light and Power Company, 284
 Harrow, Suggested Electric Lighting of, 714
 House-to-House Electric Supply Company, 976
 Incandescent Electric Lamps, The Maximum Efficiency of, 65
 Jones, Mr. H. E., on Electric Lighting and Gas in America, 628
 Kensington and Knightsbridge Electric Lighting Company, Limited, 371
 Kensington Vestry, The, and Electric Lighting, 1064
 Leamington, The Electric Lighting Installation at, 20, 157, 328, 500
 London Electric Supply Corporation, 412
 Manchester Exhibition, Lighting of the, 500
 Maxim-Weston Company's Affairs, 157, 283, 584, 628, 1020
 Metropolitan Electric Supply Company, 240, 370, 714, 797, 1019
 Miners' Safety Lamps, 628
 New Orleans, Gas Preferred to Electricity at, 714
 New York, Electric Lighting in, 371
 Offer, Mr. G., and his Interviewers, 584
 Overhead Wires, The Dangers of, 1104
 Paddington Station, Electric Lighting at, 329
 Paris, Electric Lighting in, 329, 411, 930, 976
 Paris Exhibition, Prices for Electric Lighting at the, 931
 Paris Theatre and Concert Rooms, The Lighting of the, 1065
 Parliamentary Notices of Electric Lighting Ventures, 975
 Parliament, Electric Lighting Questions in, 1104
 Picture, A Glowing, 581
 Pilsen-Joel Company, The, 65, 411, 1020
 Power, Electrical Transmission of, 499
 Precoe's, Mr., Estimate of the Cost of Electric Lighting, 456
 Provincial (Brush) Electric Light and Power Company, 241
 Provisional Orders for Electric Lighting, 65, 157
 Reading, Proposed Experiment at, 1065
 Revival, Prospective, of Electrical Speculation, 198

Electric Lighting Memoranda (*continued*)—
 Rules for the Electrical Fitting of Houses, 412
 Small Electric Lighting Installations, Cost of, 882
 South-Eastern (Brush) Electric Light and Power Company, 241
 Specification for Wiring an Electric Light Installation, 283
 St. James's, The Vestry of, and Electric Lighting, 371
 Stent, Mr. John, on Electricity v. Gas, 500
 Suez Canal, The Lighting of the, 543
 Sun Lamp, The, 672
 Thomson, Mr. William, on Electrical Supply, 930
 United States, Electric Lighting in the, 29
 Vacuum, The Power of Electricity to Produce a, 198
 Volta Prize, Award of the, to M. Gramme, 671
 Water Colours, Effect of Artificial Lighting upon, 284
 Westinghouse Company, Progress of the, 930
 Westinghouse System of Electric Lighting, 371, 543, 713, 1019
 Whitehall Electric Lighting Station, 797
 Wires, the Danger of Overhead, 1104
 Woodhouse and Rawson, Limited, 1104
 Electric Lighting Stations, 978
 Ellisson, M.—Presidential Address to the Société Technique du Gaz en France, 21
 Fires, Domestic: Their Accessories and Substitutes, 1065
 Gadd's, Mr., Spiral Framed Gasholders, 371, 544
 Gas, A Comparison between Oil and, 1020
 Gas Acts for 1888, 757
 Gas and Water Companies in the Stock Market, 19, 64, 114, 156, 198, 240, 283, 328, 370, 411, 456, 499, 543, 584, 628, 671, 713, 756, 796, 840, 882, 930, 976, 1019, 1064, 1104
 Gas Institute, Mr. Bray's Attacks upon Members of the, 242
 Gas Lighted Rooms, The Ventilation of, 66
 Gas Lighting and Picture Galleries, 412
 Gas Lighting and Ventilation, A Combined System of, 672
 Gasholder, A Three-Lift, for Sydney, 977, 1021, 1066, 1105
 Gasholder Patents, New, 544
 Gasholders, The Preservation of, from Rust, 629
 Gibbons's, Jun., Mr. B., Illustrated Catalogue, 1066
 Glasgow International Exhibition, 65, 200, 330, 458
 Golden South Africa, 1066
 Grand Junction Water Company's New Storage Reservoir at Ealing, 241
 Guide Framing of Gasholders—
 Gadd's, Mr., Spiral Framed Holders, 371
 Livesey, Mr. G., on the, 842
 New Devices for Guiding Holders, 544
 Rotherhithe Holder, The, 199, 544
 Halifax Gas Scandal, The, 586
 Hedges, Mr. Killingworth, on Central Station Electric Lighting, 978
 Ironmongers' Exhibition, The, 931
 Lawrence Gas, The, and other Similar Schemes, 500
 Legislation, Gas and Water, in 1888, 757, 842, 884
 Livesey, Mr. G., on the Guide Framing of Gasholders, 842
 London Water Supply, 159
 Manchester District Institution of Gas Engineers, 371
Mechanical World Pocket Diary and Year Book, 1066
 Methven and Sugg's, Messrs., Combined System of Gas Lighting and Ventilation, 672
 Motive Power, The Distribution of, 457
 Municipal Elections, Gas Matters at the, 883
 Oil and Gas, A Comparison between, 1020
 Oswestry, The Early Supply of Gas in, 21
 Picture Galleries, Gas Lighting in, 412
 Pole, Dr. W., on the Late Sir William Siemens, 797
 Pumps, The History and Construction of, 1066
 Reading Gas Company, The New Gas Works of the, 284
 Relic, A Historic, 21
 Residual Products, The Disposal of, 933
 Rotherhithe, A Gasholder with Partial Guide Framing at, 199
 Rust, The Preservation of Gasholders from, 629
 Saccharine as a Substitute for Sugar, 329
 Scratchley, Mr. Philip A., on the London Water Supply, 159
 Siemens, Sir William, The Life of, 796
 Société Technique de l'Industrie du Gaz en France, 21
 Society of Arts—Mr. W. J. Dibdin on Standards of Light, 1105
 South Africa, Golden, 1066
 South African Lighting Association, Limited, 931
 Southern District Association of Gas Engineers and Managers, A Gasholder Debate at the Meeting of the, 842
 Spiral Framed Gasholders, 371
 Standards of Light, Mr. W. J. Dibdin on, 1105
 Structural Design, The Observance of Type in, 115
 Sydney, A Three Lift Gasholder for, 977, 1021, 1066, 1105
 Three Lift Gasholder for Sydney, A, 977, 1021, 1066, 1105
 Type, The Observance of, in Structural Design, 115

Ventilation, A Combined System of Gas Lighting and, 672
 Ventilation of Gas Lighted Rooms, The, 66
 Wallace, Dr. W., The Late, 841
 Warrington Gas Works, Management of the, 158
 Water Acts for 1883, 842, 884
 Water and Metals, Finding, by Divination, 544, 630, 1022
 Water Colour Drawings and Gas Lighting, 412

Notes.

Action of Products of Combustion upon Steam Jets, 715
 Adulteration of Coal Tar Naphtha, The, 934, 979
 Aëration of Water Supplies, The, 285
 Air Pyrometer, A New, 413
 American Low Power Gas Engine, An, 758
 American Photometrical Standard, An, 160
 Aqua-Ammonia Motor, An, 160
 Artificial Lighting, The Problem of, 586
 Atmosphere of Workshops, The Composition of the, 201
 Boiler, An Instantaneous, 674
 Bricklaying in Frost, 459
 Brickwork, A New Waterproofing Liquid for, 63
 Bunsen Flame, Proof of the Hallowness of the, 201
 Burner, A, for Natural Gas, 459
 Burning Gas under Steam Boilers, 413
 Calorimetry of Coal, The—A Correction, 587
 Carbolu Lamp, A Flameless, 67
 Cement Concrete, The Mixing of, 979
 Cement Mortars, The Permeability of, 459
 Cement Pavements, The Composition of, 502
 Cement, The Effect of Adding Sugar to, 285
 Cement, The Strength of, 502
 Chimneys, The Oscillation of, 160
 Coal Dust, The Composition of, 799
 Coal Tar Naphtha, The Adulteration of, 934, 979
 Coal, The Calorimetry of—A Correction, 587
 Coal, The Value of Spontaneously Fired, 934
 Coke Breaker, Another, 330
 Coke, The Fuel Value of Weathered, 799
 Composition of Cement Pavements, The, 502
 Composition of Coal Dust, 799
 Composition of Good and Bad Mortars, The, 459
 Composition of the Atmosphere of Workshops, The, 201
 Compressibility of Gases, The, 674
 Creosote, The Production of, from Pine Wood, 546
 Dangers of Water Gas, The, 934
 Differential Charges for Electro Motors, 979
 Distribution of Friction in Steam Engines, The, 979
 Dry Rot in Timber, 235
 Effect of Adding Sugar to Cement, The, 285
 Electric Welding, 885
 Electric Welding, The Origin and Utility of, 243
 Electro-Calorimetry, 546
 Electro Motors, Differential Charges for, 979
 Estimating the Volume of Gas in Pipes or Flues, 586
 Experiments with Tar Fuel, 885
 Explosive, A Harmless, 23
 Filter, An Improved Water, 243
 Fireproofing Textile Fabrics and Tissues, 758
 Flameless Carbon Lamp, A, 67
 Flameless Explosive, A, 23
 Flexible Gas Tubing and Fittings, 715
 Flooring for Engine Houses, 201
 Friction, The Distribution of, in Steam Engines, 979
 Frost, Bricklaying in, 459
 Fuel Value, The, of Weathered Coke, 799
 Gas, Burning, under Steam Boilers, 413
 Gas Engine, An American Low Power, 758
 Gas, Estimating the Volume of, in Pipes or Flues, 586
 Gas Heated Rolls for Iron, 715
 Gas Lamp, The Lebrun Regenerative, 67
 Gas Making Processes, Reappearance of Old, 546
 Gas Volumes, Reduction of, to Normal Temperature and Pressure, 331
 Gaseous Mixtures, Igniting, by Incandescent Lamps, 243
 Gases, The Compressibility of, 674
 Hardening of Mortars and Cements, The, 674
 Hallowness of a Bunsen Flame, Proof of the, 201
 Hydrocarbon Vapour Generator, An, 758
 Incandescent Lamps, Igniting Gaseous Mixtures by, 243
 Instantaneous Boiler, An, 674
 Ironwork, Preserving Exposed, 934
 Lacquer for Iron and Steel, 715
 Lamp, A Magnesium Powder, 23
 Lebrun Regenerative Gas Lamp, The, 67
 Lighting, The Protection of Buildings from, 67

 Gas, Heating the Cylinders of Steam Engines by, 1112
 Gas Institute, The Meeting in London (*Continued from Previous Volume*)—
Papers Read—
 On Photometers, by Mr. W. J. Dibdin, 12
 Differential Charges for Gas, by H. Woodall, 16
 On the Latest Improvements of the Gas Balance, by Frederick Lux, 103
 The Ventilation of Gas Lighted Rooms, by John Somerville, 60
 Sanitary Influence of Heating by Gas, by Lewis W. Leeds, 110
 Gas Lamp—
 The "Meteor," 418
 The Schülke, 510
 Gas Lighted Buildings, The Ventilation of, 762
 Gas Lighting by High Power Burners, 337
 Gas Manufacture, Lectures on, at the City and Guilds of London Institute, 69
 Gas, Mr. J. Emerson Dowson on the Value of, as a Fuel, 463, 507, 802
 Gas Supply, A Relic of the Early Days of, 24
 Gas Undertakings, Mr. Alfred Lass on the Accounts of, 1023
 Gaseous Mixtures, Improved Apparatus for Testing and Analyzing, 292
 Gasholder, Destruction of a, at the Montreal Gas Works, 70
 Gasholder Guide Framing Question, An American Review of the, 759, 935
 Gasholder, The New, of the Consolidated Gas Company of New York, 937
 Gasholders, Mr. Gadd's Spiral Framed, 373, 416, 503, 590
 German Candles, The Light Giving Power of, 532
 German Gas Engineers, A Gathering of, at Ludwigsburg, 418
 Guide Framing Question, Mr. W. Mooney on the, 759, 935
 Half Depth Regenerative Furnaces, Mr. F. Bierce on, 122
 Harcourt's, Mr. A. G. Vernon, New Photometer 118
 Helps's, Mr. J. W., Pipe Extractor, 508
 High Power Burners, Gas Lighting by, 337
 High Power Gas Burner, The "Industrial," 552
 Holophotometer, The, 118
 "Industrial" High Power Gas Burner, The, 552
 Institution of Civil Engineers—
 Compressed Oil Gas and its Applications, 463
 Detection of Leaks in Water Mains, 249
 Economy of Ordinary Coal Gas as a Motive Power, 762
 Institution of Mechanical Engineers—Mr. A. W. N. Tyrell on the Rathmines and Rathgar Township Water Works, 938
 Inverted v. Ordinary Gas Burners, 762
 Iron, Professor A. Crum-Brown on the Rusting of, 720
 Lachomette, M. de, on the Manufacture of Sulphate of Ammonia, 421
 Lass, Mr. Alfred, on the Accounts of Gas Undertakings, 1023
 Leaks, The Detection of, in Water Mains, 249
 Leeds Forge, The Water Gas Plant at the, 635
 Light Giving Power of German Candles, 592

- Light Giving Power, The, of Different Gas Burners, 248, 553
 Lighthouse Illumination by Electricity, 553
 Ludwigsburg, A Gathering of German Gas Engineers at, 418
 Manchester District Institution of Gas Engineers—
 Meeting at Doncaster—
 General Business, 372, 416
 Visit to Conisbro' Castle, 416
Papers Read—
 Gasholders without Upper Guide Framing, by Thomas Newbigging, 373, 416
 Oil and other Illuminants, and their Effect on the Consumption of Gas, by James Dalglish, 374
 Meeting at Manchester—
 General Business, 380
 Discussion on Mr. J. Dalglish's Paper on Oil and other Illuminants, and their Effect on the Consumption of Gas, 1067
 Discussion on Mr. T. Newbigging's Paper on Gasholders without Upper Guide Framing, 1106
Paper Presented—
 The Presence of Water or Moisture in Coal and its Effects, by Thomas Newbigging, 981
 "Meteor" Gas Lamp, The, 418
 Mid-Rhenish Association of Gas Engineers, 418
 Midland Association of Gas Managers—
 Meeting in Birmingham—
 Discussion on Mr. J. T. Lewis's Paper on The Competition of Petroleum with Gas for Lighting Purposes, 844
 General Business, 718, 800
 High Carbonizing Temperatures, Mr. Charles Taylor on, 719, 800
 Proposed Lectures on Gas Manufacture, 800
 Montreal Gas Works, Disastrous Explosion at the, 70
 Motive Power, Economy of Ordinary Coal Gas as a, 762
 Naples, Reservoir Galleries and Conduits in, 510
 New York, The New Gasholder of the Consolidated Gas Company of, 337
 North British Association of Gas Managers—
 Annual Meeting in Glasgow—
 Committee's Report, 332
 General Business, 332, 375
 President's (Mr. David Terrace's) Inaugural Address, 204, 332
 Summary of Proceedings, 202
Papers Read—
 Automatic Gas Lighting, by Geo. Keillor, 246, 375
 Coal Tar as Fuel for Steam Boilers, by John McCrae, 245, 334
 Gas Burners for Photometrical Purposes, by Geo. R. Hislop, 205, 332
 Manufacture of Sulphate of Ammonia, by Robert Cowie, 245, 333
 Regenerative Furnaces for Small Gas Works, by John Smith, 288, 376
 Scrubbing, Condensing, and Washing of Coal Gas, by William Key, 290, 377
 Selling Gas, by Jas. McGilchrist, 287, 375
 North of England Gas Managers' Association—
 Meeting at West Hartlepool—
 General Business, 678
 Perret's Dust Fuel Furnace, 682
 President's (Mr. T. Bower's) Inaugural Address, 678
Paper Read—
 Modern Methods of Increasing Gasholder Storage, by T. Wright, 680
 North of Ireland Association of Gas Managers—
 Annual Meeting in Lisburn—
 Committee's Report, 335
 General Business, 335
 President's (Mr. E. Stears's) Inaugural Address, 335
Papers Read—
 Experience with Mr. G. R. Hislop's Regenerative Furnaces, by A. Waddell, 379
 Retort Setting for Small Gas Works, by J. Robb, 381
 Utilization of Tar at Dundalk, by W. R. Featherstone, 379
 Oil Gas, Compressed, and its Applications, 463
 Oswestry, A Relic of the Early Days of Gas Lighting in, 21
 Photometers, Mr. A. G. Vernon Harcourt's New, 118
 Pipe Extractors, Mr. J. W. Helps's, 508
 Pipes, Calculating the Flow of Water through, 983
 Power, The Electrical Transmission of, 508
 Precece, Mr. W. H., on Electric Lighting, 462
 Purifying Material, The Commercial Value of Spent, 718
 Rathmines and Rathgar Township Water Works, Mr. A. W. N. Tyrrell on the, 938
 Regenerative Furnaces, Half Depth, 122
 Regenerative Gas Lamps, 938
 Regenerative Lamps, The "Delmas" and "Ezmos," 849
 Reservoir Galleries and Conduits in Naples, 510
 Rusting of Iron, The, 720
 Schillke Gas Lamp, The, 510
 Smoke Consuming Furnace, Wilmann's, 419
 Société Technique du Gaz en France—
 Abstracts of Papers, 68, 162
 "Delmas" and "Ezmos" Regenerative Lamps, The, 849
 "Industrial" High Power Gas Burner, The, 552
 Société Technique du Gaz en France (*continued*)—
 Light Giving Power of Different Gas Burners, The, 553
 Spent Purifying Material, M. Chevalet on the Commercial Value of, 718
 Sulphate of Ammonia, M. de Lachomette on the Manufacture of, 421
 Society of Arts—Mr. W. J. Dibdin on Standards of Light, 1108
 Society of Engineers, 1068
 South-West of England District Association of Gas Managers—Meeting at Weston-super-Mare—
 Gasholders with Spiral Guides, 590
 General Business, 504
 President's (Mr. H. Sainsbury's) Inaugural Address, 549
 Summary of Proceedings, 501
Papers Read—
 A Pressure Gauge having no Fixed Joints, by A. Thomas, 590
 Hydraulic Main, The, and Retort Bench Bracing, by J. J. Jervis, 549
 Naphthalene, A Remedy for, by W. Davis, 551
 South-Western (U.S.A.) Gas Association, 719
 Southern District Association of Gas Engineers and Managers—Meeting in London—
 General Business, 843
Papers Read—
 Guide Framing of Gasholders, The, by George Livesey, 846, 887
 Some Hindrances to the Sale of Gas, by W. E. Price, 847, 890
 Spent Purifying Material, The Commercial Value of, 718
 Spiral Framed Gasholders, Mr. Gadd's, 373, 416, 504, 590
 Standards of Light—
 British Association, The, and, 506
 Dibdin, Mr. W. J., on, 1108
 Steam Engines, Heating the Cylinders of, by Gas, 1112
 Strachan, Mr. G. R., on the Average Meter System, 119
 Sulphate of Ammonia, A New Process for the Manufacture of, 421
 Syphon Water Meter, Cowan's, 982
 Testing and Analyzing Gaseous Mixtures, Improved Apparatus for, 292
 Tyrrell, Mr. A. W. N., on the Rathmines and Rathgar Township Water Works, 938
 Ventilation of Gas Lighted Buildings, 762
 Water, Calculating the Flow of, through Pipes, 983
 Water Gas Plant at the Leeds Forge, 635
 Water Mains, The Detection of Leaks in, 249
 Water Meter, Cowan's Syphon, 982
 Water Supply, Mr. W. Santo Crimp on, 592
 Western (U.S.A.) Gas Association, 25, 72, 122, 163
 Westphal's Patent Gas Lamp, 418
 Wilmann's Smoke Consuming Furnace, 419
 Wright, Mr. Lewis T.—Lectures on Gas Manufacture at the City and Guilds of London Institute, 69
- ### Register of Patents.
- [The names printed in italics are those of persons by whom patents have been communicated.]
- Abel, C. D.—
 Gas Motor Engines, 73, 206, 636
 Heating the Igniting Tubes of Gas Motor Engines, 684
 Igniting Gas Apparatus for Gas Engines, 27
 Atkinson, J.—Gas Engines, 250
 Barker, T. B.—Gas Engines, 511
 Barton, C. C.—Valves for Liquid Meters, 206
 Bennett, W. H.—Mixture and Treatment of Materials for Enriching Coal Gas, and in Removing or Preventing Stoppages in Ascension Pipes, 722

Upton, C. S.—Gas Burners, 684
Walker, C. M.—
Gas Burners, 382
Regenerative Gas Lamps, 554
Wallwork and Sturgeon—Governing the Speed of
Gas Engines, 896
Welsbach, C. Auer von—
Bunsen Gas Burners, 850
Incandescent Gas Burners, 123
Williams and Thomas—Gas Burners, 74
Wilson, C. C.—Gas Stoves, 806
Wordsworth, C. T.—Gas or other Hydrocarbon
Motors, 382
Wright, J. F. and G. E.—Gas Heated Baths, 124
Wyllie, R.—Distilling Ammoniacal Liquors, 250

Altering and Adjusting the Outlet Liquid Level
in Tanks or other Vessels—Cutler, S., 722
Arrangement of Gas Washers or Scrubbers when
more than One are Employed—Cutler, S., 722
Atmospheric Gas Burner—Saul, D. H., 554
Automatically Generating Gas from Liquid Fuel
—Brotherhood, C., 850
Automatically Lighting and Extinguishing Gas
Lamps—Schiller and Meyer, 763
Automatically Lighting Street Lamps—Kincaird,
S. B., 166
Bunsen Gas Burners—Imray, O. (*Welsbach, C.*
Auer von), 850
Carburetted Air and Enriching Gas—Herzog, C.,
465
Carburetted Gas—Doms, L., 940
Carburetted Gas Lamps—Kitson, A., 512
Cleaning or Separating Ammoniacal Liquor and
other Matters from Tar—Krayenbuhl, Peter-
sen, and Burmeister, 804
Continuous Production of Gas, The—Dempster,
J., 895
Controlling and Regulating the Discharge of
Water or other Liquid at any Head below
the Initial Pressure—Braithwaite, C. L. and
J., 896
Desulphurization of Gaseous Products—Hood and
Salomon, 123
Distillation of Ammoniacal Fluids—Davis, G. E.,
763
Distilling Ammoniacal Liquors—Wyllie, R., 250
Enriching and Burning Illuminating Gas—
Porter, G., 850
Enriching Gas—Lawrence, R. S., 1069
Gas Burners—
Haddan, H. J. (*Jackson, W. M.*), 124
Mills, B. J. B. (*Upton, C. S.*), 684
Moore, D. S., 73
Pintsch, J., 123
Walker, C. M., 382
Williams and Thomas, 74
Gas Cocks—Foster, T., 635
Gas Cooking Stoves—Greenwood, T., 636
Gas Engines—
Abel, C. D. (*Gas Motoren Fabrik Deutz*), 73,
206, 636
Atkinson, J., 250
Barker, F. B., 511
Bull and Co., H. C., Limited, 26
Davy, C., 593, 722
Dougill, J., 26
Embleton, D., 338
Griffin, S., 26
Hahn, E. J., 382
Körting, E., 73
Lindley and Browett, 338
Nash, L. H., 805
Southall, J., 250
Sturgeon, T., 804
Gas Fires and Stoves—Rhodes, S. G., 895
Gas Governors—Cole, H. W. and A. F., 1070
Gas Heated Baths—Wright, J. F. and G. E., 124
Gas Heating Stoves—Jackson, W., 722
Gasholders—Gadd and Mason, 635
Gas Lamps—
Boult, A. J. (*Lebrun and Fougeron*), 554
Cole, H. W. and A. F., 593
Fletcher and Clare, 466
Gordon, T., 206
Pugh, R. W., 511
Thomas, T. C. J., 721
Thompson, W. P.—
(*Deumel, F.*), 984
(*Hertzford, J.*), 338
Gas Lamps, Burners, and Shade Carriers—Ken-
nedy, W. W., 422
Gas Lamps and Burners—Quaglio and Westphal,
721
Gas Lanterns—Drew, H., 124
Gas or other Hydrocarbon Motors—Wordsworth,
C. T., 382
Gas Producers—Bull and Co., H. C., 165

Gas Stoves—
Meidinger, H., 684
Saul, D. H., 124
Wilson, C. C., 806
Governing the Speed of Gas Engines—Wall-
work and Sturgeon, 896
Governors for Steam, Gas, and other Fluids and

NOTICE TO SUBSCRIBERS

AS TO PAYMENT OF SUBSCRIPTIONS IN ADVANCE.

Subscribers who desire to avail themselves of the reduction in the Subscription to the JOURNAL by paying in advance for the second half of the year 1888, are reminded that this can only be done during the present month

The Subscription is at the rate of 21s. a year paid in advance, or 25s. if credit be taken.

THE JOURNAL OF GAS LIGHTING, WATER SUPPLY, & SANITARY IMPROVEMENT.

TUESDAY, JULY 3, 1888.

PAPERS AT THE GAS INSTITUTE MEETING.

THE instalment of the proceedings of The Gas Institute which we publish to-day consists of the papers read by Mr. W. J. Dibdin and Mr. Henry Woodall, with the discussions thereon. As in the cases of Mr. Carpenter and Mr. Valon, the discussion on Mr. Dibdin's paper tended to wander from the author's points, and to deal with others put forward by the speakers themselves. Mr. Dibdin treated of photometers; and most of the speakers persisted in talking of standards of light and similar topics connected with photometry, but by no means entering into the question of the design and construction of the photometer itself. This remembrance brings us back to a proposition that has been frequently made, but never acted upon—that prints of the papers presented at The Gas Institute meetings should be distributed in the room

when the authors rise to read them. It is to be hoped that the Council of the Institute will take this proposal into serious consideration before the next meeting. There are no objections to it whatever, that can be named in the same breath with its many recommendations. The members of the Council at present have the advantage over the ordinary members, in being able to follow the readers through all their arguments and calculations, without being thrown out by any of the common hindrances to appreciation of the author which so frequently spoil the best papers. It is not every writer who is at the same time a good reader; but, apart from this consideration, a man may have a weak voice, the acoustic properties of the hall may be poor, or one of his best points may be lost to a portion of his audience through some momentary interruption. It is to be earnestly hoped that the Council will take up this question at the proper time, and apply the solution we have indicated, which would be a popular as well as a reasonable reform in the management of the Institute meetings. It would be the most effectual way of keeping speakers in a discussion from that misunderstanding of a writer's point which infallibly leads to a wandering and purposeless debate.

To return from this digression respecting the reading of papers in general, to the subject of Mr. Dibdin's paper. As we have already had occasion to remark, when referring to the paper, it is principally an indictment of the Evans photometer, and indirectly of all closed photometers of any pattern. It is a noteworthy fact that the Evans form of this most important instrument is seldom met with out of London. Mr. Dibdin tells us how the pattern came to be designed by the late Mr. F. J. Evans in the first place, and how it was afterwards adopted as a legal gas-testing instrument by the Gas Referees. Its chief recommendation was the fact of its being self-contained; thus rendering a dark room unnecessary. But the supposed advantage is easily overrated; and its drawbacks are, as Mr. Dibdin confesses, serious. The worst of it is that while the apparent advantage of this instrument is very obvious, its disadvantages are occult, and only to be discovered by long experience. It is rather a favourite with those who like an important-looking instrument; but it is responsible for much of the trouble respecting candles that has perplexed photometrists and gas makers of late years. It was decidedly hard upon the makers of photometers that after Mr. Dibdin had pointed to the new "Tower" or "Imperial" pattern of the instrument as being the best of its class, Mr. George Livesey should have been compelled to denounce it as the means of making the South Metropolitan Company waste £2000 worth of cannell last year in the endeavour to obtain a good record. Mr. William King, of Liverpool, clearly showed that the complication of photometer construction is an evil, and claimed the credit of the first simple and efficient form of this apparatus for his father, the late Mr. Alfred King. Apart from this personal question, there is doubtless very great force in Mr. King's advice to operators to keep to the simplest forms of the apparatus; but unfortunately there is about the photometry of gas-flames a certain unavoidable complication, arising from the necessity for standardizing the burners, measuring the quantity, and controlling the pressure of the gas consumed, which renders well-made and reliable appliances imperative. All this accessory apparatus has come to be associated inseparably in ordinary minds with photometry itself, which is essentially a simple matter. The difficulty with many observers, who might otherwise feel disposed to follow Mr. King's advice, is to decide between essentials and non-essentials. We cannot attempt to determine the comparative merits of different forms of photometers, when the most eminent authorities take conflicting views respecting them. It is necessary, however, that attention should be drawn to the emphatic condemnation of the methods of gas testing legalized for the Metropolis by the Gas Referees, with which Mr. Dibdin closed the debate upon his paper. Anything more sweeping than this denunciation of the system under which, as Mr. Dibdin declared, the London gas examiners are "compelled to "commit a nightly fraud with the knowledge of the authorities," has never been printed.

Mr. Woodall's discourse on differential prices for gas has been discounted by his many published utterances upon the same and cognate subjects. It began with a clear statement of the error of Local Authorities who make, out of their gas-works, profit which they apply in the reduction of the local rates—a proceeding which the author described as taxing the few for the benefit of the many, and taxing trade for the relief of property. There is no reply to this indictment; but

unfortunately, the men who commit the error do not profess to argue the point—they merely put their hand into the till and take the money. Upon the question of differential prices for gas, it cannot be said that either the paper or the discussion upon it was particularly instructive. There are two orders of differential prices for gas—one based upon the quantity of gas consumed, and the other upon the purpose or the time of the consumption. Although Mr. Woodall had each of these orders of differences in mind, and mentioned them both, he did not distinguish between them sufficiently to lead the discussion to any clear issue. The arguments for differential prices for gas on the basis of quantity consumed, are simply those which give the wholesale buyer an advantage in price in respect of every other commodity, and are accordingly unanswerable. We have never favoured the extension of too much consideration to large consumers; but so long as the customs distinguishing wholesale from retail trading remain in force, they will continue to be applied in dealings in gas as in other articles of commerce. With regard to the desirability of differential prices on account of differences in purpose, time, or method of consuming gas, the consideration of this problem entails the valuation of special factors which are half commercial and half technical in character. This problem was not touched in the discussion on Mr. Woodall's paper, for which, as already remarked, the author was partly responsible. The paper was undeniably interesting, as anything coming from Mr. Woodall is almost certain to be; but it somehow lacked point, as well as being noticeably deficient in weight of matter. The author has not of late had much to do with selling gas at differential prices; and although the paper was an example of the proneness of a gas engineer to "return to his first love," like other men, it was also an illustration of the ugly truth that first loves are apt to pall upon a man in time. There is nothing more that need be said upon this paper for the present.

THE PAY AND POSITION OF GAS ENGINEERS.

DURING the last few weeks there have been several changes in the occupancy of leading positions in connection with the British gas industry; and there may be more to follow. We have declared our intention of keeping the question of the pay and position of gas managers in England well under notice; and therefore take this opportunity of returning to it, *à propos* of recent events. The removal of Mr. Lewis Thompson Wright to Buenos Ayres—to which rapidly expanding field of labour Mr. Wright will carry the good wishes of all his professional colleagues who have watched his promising career—creates a vacancy at Nottingham; and we are pleased to note that the Nottingham Corporation Gas Committee have followed the good course of announcing the salary which is attached to the appointment, instead of putting it up to a bidding by private tender. If it cannot be said that in offering £600 a year to commence with the Nottingham Committee display noticeable liberality, the figure is at least respectable. The Directors of the Bristol United Gas Company have taken a fresh departure in their system of administration, by advertising for station superintendents and chemists, which cannot be regarded with favour by anyone who is properly solicitous for the interest of the gas engineering profession in general and of this Company in particular. It is all very well to have a full and efficient staff of works superintendents; and a chemist is a good addition to the administrative department. The Company also deserve credit for advertising the amounts of the salaries they mean to pay their station managers. Here, however, approval of their policy must end. They are committing the grave error of trying to do without a head, like the Manchester and Leeds Gas Committees; and, like these, they will regret it some day. A system of administering a large gas undertaking having several stations, consisting of a republic of mutually independent superintendents working under a clerical head, has its superficial and temporary recommendations—especially to the clerical head—but it is certain to break down in the long run. Nobody in the concern has sufficient authority to direct the undertaking as a whole; and so, after a shorter or longer time, depending upon local circumstances, a consulting engineer will have to be called in to set matters straight, regardless of expense. Again, one is at a loss to know why Bristol wants three chemists—if these officers are to be worthy the name, and are not to be merely routine gas testers. Surely it would be more in accordance with common sense to confide the executive work to a duly qualified and properly paid chief engineer; giving him his necessary staff of station superintendents and

one capable chemical assistant. We offer this criticism on the policy of the Bristol Gas Company principally on general and public grounds, but also in the interest of the undertaking. It is quite possible that somebody may think we are answered by saying that the Bristol or any other Board of Directors should be permitted to do their own business in their own way; but the question is too important and too public in its nature to be disposed of in any such manner. A gas undertaking is a branch of the public service; and it is essential that the men who from time to time are entrusted with the guardianship of a permanent department of the service should be reminded of their duty. Boards of Directors and Corporation Gas Committees come and go, and nobody remembers them; but the effects of their wisdom and folly, chiefly displayed in the choice of capable or incapable executive officers, endure for generations after they have been personally forgotten, in the undertakings of which they have had temporary control. There are towns in England whose inhabitants have to pay half as much again for their gas as need have been charged, simply because of the blunders or some bygone magnate of the Board who carried everything in his own way while he lived, and never suspected what a legacy of trouble he was providing for his successors. We do not say that, in the case of Bristol, the Board are knowingly regardless of the future; but we hold that, by whomsoever advised, they are wrong in depriving their undertaking of a responsible engineering head, and maintain that if the present Board do not survive to discover their error, the revelation will come to their successors, probably at some particularly awkward time.

THE CIRCULAR INQUIRY NUISANCE AGAIN.

A FURTHER illustration of the extent and virulence of the "circular of inquiry" plague has reached us during the past week. This time it is a list of questions relating to gas-retort stokers, and emanates from the Secretary of an important Gas Company in the West of England. The matter is to be read in conjunction with the remarks contained in another paragraph relating to the attempts that are being made in some quarters to abolish engineers, and administer gas undertakings of respectable magnitude by the aid of a clerical staff and a few works superintendents. The circular now in question contains nine questions intended to ascertain the pay and work of stokers and firemen, and would be harmless enough if addressed by an engineer and manager to his professional friends. As a means whereby a Board of Directors and their Secretary hope to be able to do without the services of the officer who should be responsible for the carbonization work of their business, however, it is objectionable in the highest degree. Several copies of the circular have been sent to us from different parts of the country; from which we judge that it has been distributed broadcast. We hope that very few replies will be sent, as a hint to the Company to make arrangements for doing their business in a proper manner. Engineers and managers will have themselves to thank if they give any assistance to a policy aimed at their own extinction. It is a curious indication of the confused sense of duty prevailing in the mind of this particular inquirer that, although he signs his letters as Secretary, he addresses them to engineers and managers. Why does he not send them to his fellow-secretaries? Because he knows very well that the subject-matter is none of their business; and it should not be any of his. We shall have great pleasure in receiving any other specimens of circular-letters which the recipients have reason to regard as unwarranted, and shall duly gibbet them as they deserve. At the same time, the most effectual cure for this evil is to regularly deposit all such objectionable letters in the waste-paper basket; and this course we unhesitatingly say should be followed with nine out of every ten of these communications.

THE DEMAND FOR COKE.

If anybody can give a rational explanation of the cause of the increased demand for coke that set in last autumn, and has since been maintained, to the depletion of the stores in most British gas-works, it would be welcomed in these columns. The report of the Birmingham Gas Committee, presented at to-day's Town Council meeting, shows that all the quantity of coke in stock on June 21 at the stations of the department was only 763 tons, whereas at the corresponding period last year there were 19,124 tons unsaleable. Doubtless when the accounts of the principal Gas Companies come to be made up for the half year that has just expired, they will show a similar result. It would be interesting to know the reasons for this remarkable change, because at present it looks like

one of those unaccountable vagaries of trade that confound the most prescient men of business. Who would have prophesied, this time last year, that before another twelvemonth had passed the too-solid mountains of coke that cumbered the ground in nearly every gas-works in the kingdom would have melted away, and that prices would be raised accordingly? Yet it is precisely this power of foreseeing business fluctuations that is the most valuable possession of the trader. In this matter of coke, however, demand seems to rise and fall for no reason that the keenest-sighted dealer or producer can distinguish. All we know at present is that whereas last year there was plenty of coke in stock, this year there is none; but what has really brought about the change is a mystery. People talk glibly enough about times of good trade and bad trade; but very few can recognize the broad signs of either condition while they actually exist, to say nothing of foreseeing their appearance. Most men can only be certain about such matters after the time has passed. We can look back upon the extraordinary advance in the value of coal and iron of twelve years ago or thereabout, and remark that anybody who could have foreseen what would happen at that time could have made a great fortune by forestalling the rise. Many did so; but the process was more accidental than deliberate. Many buyers of coal and iron then took credit to themselves for their cleverness in making contracts for future supplies on good terms for themselves; but people who once happen to make a good shot in this way, are liable to try the same thing once more, and make a disastrous failure of it. Over and over again during the past ten years there has arisen a cry of a general revival of trade, and a warning of a rise in the value of staples as a necessary consequence. Nothing has come of it, however, and speculators for the rise have done no good, even where they have not seriously damaged themselves. Now, comparatively unnoticed by newspapers, and unattended by any remarkable change in the aspect of the national industries, the demand for coke has swelled and swelled—gradually, imperceptibly, and irresistibly—until it has swallowed up the available supply. The unaccountableness of the phenomenon recalls to mind the fancy of the philosopher who connected crises and periods of expansion in the world of finance with the appearance and absence of sun-spots. People must have a reason for movements that they see going on around them in the affairs of trade and industry, even if nothing nearer than the planetary system presents itself. The Goodwin Sands have been ascribed to the influence of Tenterden Church steeple; and have the recent changes in the occupancy of the Imperial throne of Germany had anything to do with reducing the stock of coke in the United Kingdom? If not, to what is this change due? The question is far easier asked than answered.

Water and Sanitary Affairs.

THE action brought by the East London Water-Works Company in the City of London Court, a report of which appeared in the last number of the JOURNAL, points to a practical inconvenience in the working of Mr. Forrest Fulton's Act. Primarily, the person "using" the water supplied by a Company is liable to pay for it; but in the cases which come within the operation of the recent Act, the short and simple remedy of cutting off the supply in the event of non-payment, has been forbidden. In the action referred to, defendant was occupier of premises where the Company's water was consumed; that is to say, he was allowed to live there by his employer, a contractor, whose name was persistently concealed from the Company. In these circumstances, how was the water-rate to be recovered, and from whom? The Company brought an action against the defendant, the actual occupier. Ultimately, under the pressure of Commissioner Kerr's remarks, the full name and address of the mysterious contractor were admitted, and he was made a co-defendant in the action. In this case, therefore, the Company probably will overcome the obstacles placed in their way, and in the end the rates will be recovered. Nevertheless, the hardship of the position is apparent. It cannot be doubted that if the Company had been at liberty to cut off the water, the knowledge that they possessed that power would have led to payment of the rates without the expense and delay involved in taking legal proceedings. Even so, but for the peremptory direction of the learned Commissioner (a direction which it would seem by no means easy to enforce against an obstinate defendant), justice would still have been balked. Mr. Fulton's Act has

thus opened a way for fraud and deception, against which the Water Companies are almost powerless. It is true that payment in advance can be required for the first quarter's water supply; but afterwards there is nothing to prevent a dishonest consumer getting in arrear, and "dodging" the lawful claims of the Company.

The question whether an over-payment of water-rent can be considered a compulsory payment, and therefore recoverable by the consumer, was recently dealt with in the form of a test action in the Burnley County Court. The case was reported in the JOURNAL for May 22 last (p. 992); and some editorial remarks with respect to the controversy appeared in the JOURNAL for the following week. We then ventured to express the opinion that the return of any excess of water-rent, received by a Company or Corporation in the circumstances mentioned, could not legally be claimed in an action by the person who paid it. It is satisfactory to find, from the judgment which appears in another column, that this view has been sustained by Justices Cave and Wills, who heard the appeal from the Burnley County Court in the particular case referred to. The Burnley Corporation had charged one of their customers a sum calculated at the rate of 5 per cent. on the gross rental of the house in his occupation, the amount of the rate on that basis being £8 15s. 4d. The sum, if calculated with reference to the rateable value, would have been £7 3s. 10d. The plaintiff paid the larger amount, and then claimed to recover the difference—viz., £1 11s. 6d.—on the ground that, legally speaking, the payment had been made under duress. The County Court Judge arrived at the conclusion that this contention was well founded, simply because the Corporation possessed the power to cut off the water supply. It was not suggested that they had actually threatened to cut it off. In view of this fact, it is not surprising that the Corporation should have submitted the case to the decision of the Judges of the Queen's Bench Division—a decision which, we apprehend, must be taken as finally settling a point of no small importance to Water Companies, and, if the term is permissible, Water Corporations, in general. The position certainly would be very serious if, after accounts had been closed and dividends distributed, consumers could "spring" on shareholders or ratepayers demands for sums of money which in previous years had been voluntarily paid and received in good faith as being the rates authorized by law. The Judges have now made it perfectly clear that this cannot be done; and by virtue of their ruling have put a check on the flood of vexatious litigation which might probably have broken forth if the decision of the County Court Judge at Burnley had proved to be sound law. At the same time, it is desirable that the effect of the learned Judges' decision should not be over-estimated. They have simply held that the mere possession of power to cut off water supply was not enough to sustain a plea of duress, and enable the consumer to claim a return of what he professed to have paid under some sort of compulsion. In the Burnley case, as already pointed out, there really was no compulsion at all. Not a word was said about cutting off the water if respondent failed to pay the full sum claimed; and, therefore, the payment of the amount was obviously voluntary. Regarded as a test action, brought for the purpose of raising an undoubtedly important point, the case selected was surprisingly weak. It would be easy to conceive an instance in which the circumstances could be made to wear the aspect of at least partial compulsion. The Companies, therefore, should exercise the necessary tact in avoiding disputes to which there might not be a favourable issue. In the case of many provincial undertakings, doubts still exist (owing to the varying phraseology of Special Acts) whether the water-rates are properly assessable on the gross estimated rental or on the rateable value of the premises to which the supply is furnished. At Burnley, the former was the footing on which the rates were claimed and paid for many years. Recently, however, the Corporation appear to have arrived at the conclusion that their mode of charging was erroneous. The same kind of thing may occur elsewhere. But in those instances in which doubts exist, it would obviously be bad policy to provoke or hasten a contest; nor should Directors be in a hurry to give away the rights of those whose interests they hold in trust. "Annual value," as we have before insisted, is not a term which is to be construed with reference only to the Dobbs definition. There is much in the remarks made by eminent Judges in the more recent cases, to encourage every Water Company to await a legal interpretation of their own Special Act before relinquishing a large portion of their annual income.

The Gas Institute.

PROCEEDINGS AT THE TWENTY-FIFTH ANNUAL MEETING.

CHARLES GANDON, Esq., M. Inst. C.E., PRESIDENT.
PAPERS AND DISCUSSIONS.

(Continued from Vol. LI.)

PHOTOMETERS.

By W. J. DIBBIN, F.I.C., F.C.S., Chemist and Superintending Gas Examiner to the Metropolitan Board of Works.

At the present time, which may be called the transition period in photometry, both with regard to the standard of light and the instrument with which that standard is used, there are few more vexed questions demanding the serious attention of gas managers and examiners than that connected with photometers. The various departures which have been made from time to time from the simple open bar of Bunsen, have brought about a condition of things in regard to photometers which demands careful consideration, in order that, in the changes evidently imminent, they may be distinctly understood, and that the new instrument, whichever one may be finally adopted, should give accurate results, and thus renew the confidence of all in the work done—a state of things which cannot by any means be said to exist in all cases at the present time.

In order that the present paper may have a practical value, it is not now proposed to discuss photometers other than those founded upon the principle of the Bunsen bar, both open and closed. The instruments thus referred to comprise the simple bar, either of the Letheby or Keates type, the Evans closed photometer, the "Canadian," and the recently-introduced "Imperial" standard. The "Radial" photometer when used for horizontal rays, being an open bar of the simplest type, will naturally fall under this head.

The simple bar photometer is so well known that little description of it is required. Shortly, it consists of a bar 60 inches in length in the Letheby form, or 75 inches in the Keates; having the gas-flame fixed at one end, and a candle balance with the candles at the terminal point at the other—the disc being placed in a sighting-box, which freely travels on wheels along the bar. As used by both Letheby and Keates, this instrument was employed in a room darkened during the testings. For the supposed better protection of the candles from draughts, a box was placed so as to enclose them, with the result that at times this "protection" has a deleterious effect on the candles by excessive heating of the contained air. For the purpose of avoiding the necessity of darkening the experimental room, and to comply with the requirements of the Standards Department of the Board of Trade, when certifying this instrument for the Canadian Government, the whole of the apparatus—viz., the meter, governor, bar, &c., were enclosed in a small wooden room, and shut in with heavy curtains; and in this form it is known as the "Canadian" photometer. From this it is seen that the Canadian photometer is merely a Letheby bar enclosed in a small portable room, which requires most careful ventilation to ensure accurate results, especially when candles are employed as the standard.

In 1858, in consequence of a dispute with the St. James's Vestry as to the illuminating power of the street lamps, it was decided to test the burners in use *in situ*, as the authorities at that time would not consent to the removal of the burners to a proper testing-room. Under the direction of Mr. F. J. Evans, then Engineer to The Gaslight and Coke Company, a closed photometer was constructed, and mounted on a platform in Piccadilly. The end of this photometer was constructed of such a size that it could be placed bodily over the street lamp. The disc was fixed at a point 50 inches from the flame, and the candles mounted on a travelling holder on the reverse side of the disc, and moved for the purpose of taking the readings by means of an endless cord and winch-handle, situated immediately in front of the disc. Falliug doors were fitted for affording access to the burner, disc, and candles respectively. As the testings had to be conducted in the open air, care was exercised to regulate the draughts to the gas and candles; and exit for the burnt gases was afforded by chimneys over the two ends of the box. This system evidently gave such satisfactory results to the inventor that, when he was appointed one of the Gas Referees under the Act of 1868, he so strongly advocated its use at the legal gas-testing stations, that it was adopted, and first fixed at the Arundel

Street, Leadenhall Street, Cannon Street, and Gray's Inn Lane testing stations in 1869. The gas made at Bow Common was at the same time tested with an open Letheby photometer at Friendly Place, Mile End Road; and it continued to be so tested until January, 1881, when this gas was tested with an Evans's photometer at No. 3, Jewry Street. Previous to this, however, the gas supplied by the City of London Gas Company, The Gaslight and Coke Company, and the Great Central Gas Company was, under the Act of 1860, carried into No. 37, Jewry Street, where the late Dr. Letheby tested the several supplies by an open bar photometer from about 1862 to 1868. So that at this time there was by no means unanimity of opinion as to the respective merits of the two forms of apparatus. Since then, station after station was fitted indifferently with one or other of these instruments. In 1876, two stations prescribed by the Gas Referees were fitted with the open bar; but in 1878, in consequence of the complaints of the Company as to the low results obtained by the Official Examiner, the Gas Referees consented to the removal of these two photometers, and the substitution of the Evans closed form in their place. The following are the average results obtained during 48 days before and 48 days after the alteration:—

	Station A.	Station B.
Before	17.0	16.1
After	17.5	17.1

As originally constructed for the gas-testing stations, the Evans photometer was ventilated by the two chimneys, one at either end. Subsequently objection was taken to the deficient ventilation thus afforded; and a long inverted box-cover, open downwards throughout the length of the instrument, was fitted in their place, with the view of ensuring more perfect exit for the products of combustion than had hitherto been obtained. For the same reason, the internal width of the box enclosing the flames and screen was enlarged. When, however, the new arrangement was applied to one of the existing forms, it immediately became apparent that a change for the worse had been made, as before the alteration somewhat reasonable results were obtainable; but afterwards it was almost impossible to get a test within 10 per cent. of the admitted value of the gas, and results of above 25 per cent. were by no means uncommon. The following series of tests recently made in rapid succession, by no less than six of the most experienced photometrists of the day, will show the utter unreliability of one of these converted old-pattern Evans photometers:—

Height of Gas-Flame, Three Inches.

Bunsen Disc.	New Candles and Diddin's Leeson Disc. Candles.
18.8	19.7
21.9	20.0
20.0	20.0
21.3	—

These were amongst some of the worst results given; but were by no means of uncommon occurrence.

For the purpose of thoroughly trying the question, I have at various times made careful comparison tests of three Evans photometers with a simple bar photometer used in the open without screens of any kind, other than those necessary to avoid errors due to reflection, and the protection of the observer from direct rays. The following are the results so obtained:—

Photometer No. 1	First day	Evans' Photometer. Candles.	Open bar. Candles.
"	Second day	16.0	16.3
"	"	16.5	16.4
"	Third day	15.3	15.3
"	"	17.2	17.3
"	"	16.8	16.0
"	"	18.0	16.0
"	"	17.6	16.6
"	"	16.0	16.5
"	Fourth day	16.3	16.2
"	"	16.8	15.5
"	Fifth day	16.3	15.9
"	"	16.7	16.2
"	"	17.0	16.0
"	"	17.5	16.5
"	"	15.7	14.2
Photometer No. 2	Sixth day	17.3	17.3
"	"	18.5	17.1
"	"	16.6	17.1
"	Seventh day	17.1	16.3
"	"	16.9	16.7
"	"	17.2	16.3
"	"	16.4	15.7
"	Eighth day	17.1	17.2
Photometer No. 3	Ninth day	18.7	15.9
"	"	18.7	16.0
"	"	19.1	16.0
"	"	19.3	16.0
"	"	19.8	15.9
"	"	20.7	16.0

Photometer No. 3.	Tenth day.	Evans Photometer.		Open bar.
		Candles.	Candles.	
"	"	18.3	..	15.8
"	"	18.3	..	15.8
"	"	18.6	..	15.9
"	"	18.4	..	15.9
"	"	19.5	..	15.9
"	"	20.8	..	15.9
Average		17.1	..	16.2

From these results, it is seen that the average by the Evans was 0.9 candle over that indicated by the open bar. As the instrument No. 3 had afforded such high results, I conducted a special series of tests with that one, with the following results :—

“ Evans ” Photometer No. 3, with the Wooden Top off, but with Zinc Gauze Screens remaining on.

	Evans Photometer Candles.	Open Bar Candles.	Height of Gas Flame, 3 inches
First day	17.6	16.2	..
"	17.3	16.1	..
"	17.9	16.2	..
"	18.2	16.2	..
"	17.9	16.2	..
"	18.2	16.2	..
Second day	16.3	15.0	2½ inches
"	16.6	14.9	..
"	16.9	15.0	..
"	17.2	15.1	..
"	17.4	15.0	..
Third day	17.5	15.1	..
"	17.0	16.2	3 inches
"	17.4	16.1	..
"	17.7	15.9	..
"	17.9	16.0	..
"	17.7	16.1	..
"	17.8	16.1	..
Average	17.5	15.8	

The zinc gauze was next removed, so as to convert the photometer into an open one, as far as possible ; and the following results found :—

Evans Photometer No. 3, with Wooden and Zinc Tops off.

Evans Photometer Candles.	Open Bar Candles.
15.6	15.5
15.4	15.8
15.7	15.5
16.3	15.8
15.6	15.5
15.6	15.8
Average	15.7

These results are only typical of a large number of others ; one special series of over 90 having been conducted at the request of the Metropolitan Gas Referees, with the result of most fully endorsing the indications shown above as to the behaviour of photometer No. 3—viz., that the removal of the wooden top is a decided advantage. Previously to its removal, 19 and 20 candle gas was often indicated ; while, after its removal, these results fell to between 17 and 18 candles, and again dropped on the removal of the gauge screen to about 16 candles—the tests being far more concordant in the latter case. The errors due to candles were avoided as far as possible by the use of those of two different makers and different packets.

The moving of the candles in the Evans photometer has long been admitted as a serious error ; and at the request of the late Mr. Keates, Messrs. W. Sugg and Co. constructed a modified Evans photometer, in which the candles were fixed as in the bar, and the screen was made moveable. Since then, this form of instrument has been modified. Two large towers are now placed, one at each end, for the reception of the candles and gas-burners respectively ; and the disc is moved. The tower or Imperial photometer, as this new pattern is called, has been sanctioned by the Gas Referees ; and two of them are in use in the Metropolis. The results obtained with it are far more concordant than with the old pattern Evans ; and the indications of candles agree as closely as can be expected with those afforded by the ten-candle test, which I have elsewhere shown to be a very reliable standard when used with 16-candle gas, or an inferior gas carburetted with pentane. Comparative tests with the bar photometer used in the above detailed experiments have also given very satisfactory results ; so much so, that I have no hesitation in advocating its use, if it is considered desirable that a closed photometer should be necessary.

Up to a short time back, it was always assumed that the errors of observations were invariably due to candles. The series of tests now given demonstrate conclusively that in a large number of instances candles “ have been more sinned against than sinning,” by being used in an instrument which has rendered it impossible for them to yield the results they would otherwise have done. In many of the above tests, the

same candles were used, being carefully transferred from one photometer to another, as also were the standard burners. The meters were carefully compared, and found to give identical measurements of the gas burnt ; while the height of the gas-flame was the same. The erratic behaviour of the candles in a large number of cases when used in the “ Evans ” photometer was doubtless due to the elevated temperature and vitiated atmosphere, as, when the doors of the instrument were kept open, or repeatedly opened during a test, the readings were more uniform.

The outcome of the numerous experiments which I have now conducted is that the Evans photometer, even at its best, is a most unsuitable instrument for practical photometry ; that if a Bar photometer is to be used, it should be perfectly open ; but that if a closed instrument is deemed preferable, it should be of the Imperial or tower (as it has been called) type, in which the opposing flames are placed in a large area, in which a considerable volume of air is moving at a slow speed, free from side or top draughts.

Recently I had an opportunity of demonstrating the principle in connection with one of the ordinary Lethby photometers, in which the flame was placed in a partially closed chamber—viz., closed on three sides, and partly so in front by means of a glazed window. In using such an instrument in connection with my recent experiments on the standards of light, I found it of considerable advantage to cover the top of this chamber, leaving a 6-inch circular opening for the exit of the vitiated air, and to close the part left open over the glazed front. The result was to immediately steady the flame in a manner similar to that in the tower photometer ; and far more concordant results were indicated in consequence. One outcome of this steadying the flame is that the readings are made with much greater facility and accuracy.

In the new pattern photometer I have introduced an improved form of disc-holder, in which the disc and mirrors are reversed, without the removal of the frame from the box, as in the Evans ; and consequently readings are more reliable, as the trouble of turning the disc is so slight that there is no reason why one-half should not be taken with the disc and mirrors in one position, and the remainder with them reversed. This disc-holder can, of course, be fitted to other photometers.

It may possibly be thought that, in view of the near approach of a change in the standard of light, the considerations arising from the behaviour of candles have little weight. This would indeed be so but for one fact, which has hitherto not received the attention which its importance deserves, and which is of the utmost consequence in connection with any one of the proposed substitutes for candles, and especially so with the pentane air-gas flame of Mr. A. Vernon Harcourt. This point is the steadiness of the flame. The arrangements for the ventilation of the Evans photometer render it impossible that any gas-flame should burn steadily in it. In the tower photometer the steadiness of any flame, even the pentane, is most remarkable, so much so that the confidence of the operator in the accuracy of his results is greatly enhanced ; and he feels that at last he has an instrument which is worthy of his best endeavours.

I have to acknowledge my indebtedness to Mr. A. F. Damon, one of the Metropolitan Gas Examiners, for his valuable services in connection with many of the experiments mentioned in this paper.

Discussion.

The PRESIDENT said that Mr. Dibdin, who had always been a great advocate for the improvement of the standard of light for photometry, had put forward the opinion (with which he quite agreed) that candles, although not perfect, were not so bad as they had been made out by many persons to be. His experience was that if candles were carefully and properly used, very uniform results might be obtained. In saying so, he did not wish it to be inferred that an endeavour should not be made to obtain a better standard, because it must be admitted that candles were liable to be irregular and uncertain ; but at the same time, he thought closed photometers were entirely unsuited for candles. He was sure the members would pass a vote of thanks to Mr. Dibdin.

Mr. GEORGE LIVESY (London) thought it was not possible, in the short time at their disposal, to go into a discussion on standards of light ; but they should confine themselves to the question of photometers, which was the subject of the paper. He joined with Mr. Dibdin in condemning the Evans photometer, which he had never liked, and did not know why it was introduced ; but he had an instinctive prejudice against boxing up two of the lights in such a small

coffin kind of apparatus. What the gas companies wanted was a fair and just measurement; and he was quite certain they all desired to give in illuminating power all that Parliament required. As a proof of this he might take the fact that invariably—putting aside accidental circumstances—the gas companies always gave considerably more light than was really necessary. It was to their interest to do so—to deal fairly and liberally with their customers. This being so, it was essential that they should have a photometer which would give reliable results, which he did not think the Evans photometer did. Still, he was not going to adopt the tower photometer, which he should condemn nearly as strongly as the Evans. That instrument cost the South Metropolitan Gas Company last year at least £2000 for extra candle; for they had to make 18-candle gas, and then they could not show 16 candles in the tower photometer. Why it was, he did not know; but whether it was the restriction of the air supply, or whatever it might be, there was the fact, and, do what they could, they could not keep up the quality. It was constantly just on the 16-candle standard—sometimes below; rendering them liable to penalties for deficiency of light. The most experienced of the gas testers had tried it; and at last a very high authority in testing (whose name he would not mention), with the Official Gas Examiner, brought out results very much in excess of those which the latter had been in the habit of producing. Perhaps the gas examiner, finding that a leading photometrist obtained results so very different from his own, thought he might have been wrong in his reading. However, it was sufficient to condemn the instrument if two men, or a number of men, obtained varying results from it. He did not like the boxing in at all; and he was very pleased to see that Mr. Dibdin put in the word “if”—“if” he said, “a closed instrument is deemed ‘preferable, it should be of the Imperial or tower type.’” Further on he told them of another one which was not a closed photometer, but as open as it could be, in order to meet the convenience of not having an entirely darkened room. This was how he described it: “Recently I had an ‘opportunity of demonstrating the principle in connection ‘with one of the ordinary Letheby photometers, in which ‘the flame was placed in a partially closed chamber—viz., ‘closed on three sides, and partly so in front by means of ‘a glazed window. In using such an instrument in connection with my recent experiments on the standards of ‘light, I found it of considerable advantage to cover the top ‘of this chamber, leaving a 6-inch circular opening for the ‘exit of the vitiated air, and to close the part left open over ‘the glazed front. The result was to immediately steady ‘the flame in a manner similar to that in the tower photometer; and far more concordant results were indicated in ‘consequence. One outcome of thus steadying the flame is ‘that the readings are made with much greater facility and ‘accuracy.’” That was his (Mr. Livesey’s) idea of what a photometer should be—one which would give fair results in the hands of varying operators, and under all the ordinary circumstances.

Professor FOSTER (London) remarked that, as far back as September, 1871, there was a short article by himself in the *Chemical News*, which he believed was the first published account in which this question of the Evans photometer was taken in hand. The remarks then made were just as applicable at the present time. Dr. Letheby was at Worthing; and he was in correspondence with him about another matter connected with the supply of the South Metropolitan Company. After referring to that matter, Dr. Letheby thanked him (Professor Foster) for the copy of his notes on photometry, which he said he had read with much interest; that he had done some good by pointing out the error from abnormal combustion of candles in the closed chamber of the Evans photometer; that he had himself repeatedly observed the like increase in the illuminating power of the gas towards the end of the experiment; and that in one case the illuminating power was actually more than double towards the end of the experiment, and the candles seemed to be, as it were, stifled for want of air. But this was not the only objection to the Evans form of instrument. It was too long, seeing how the light diminished with distance; its sides reflected light when dusty; the air of the chamber became too hot for proper combustion; and the ventilation was imperfect. Further, the movement of the candles affected the steadiness of their combustion. Dr. Letheby added that he did not, for obvious reasons, like to enter into a criticism of the instrument especially as his own photometer was in some sense a rival instrument. He referred to this letter, because it showed

clearly what Dr. Letheby’s experience was. His (Professor Foster’s) own experience was that an open bar, if it could be arranged, was the most convenient form—taking care, of course, that there was no particular reflection from the sides of the room, and no unsteadiness produced by draughts. There was certainly something in what Dr. Letheby said about the length of instrument for ordinary 16-candle gas. One could not lay down any very definite rule; and for testing high-power burners one required the disc at a certain distance, as one must not have more than a certain amount of luminous energy per unit area of disc; otherwise it was very difficult to read the slight differences which occurred in the observations.

Mr. WILLIAM KING (Liverpool) thought the discussion very forcibly illustrated the wisdom of the old saying—“Why ‘cannot you let it alone?’” It seemed to be forgotten that the instrument was really invented by the late Mr. Alfred King; and the photometer was an open bar in an open room, fitted with as little apparatus about it as possible. The discussion no doubt showed that these first principles would be wisely carried out at the present time; and that all the “coddling,” so to speak, which the instruments had received during the last 20 or 25 years in the way of reflectors, boxes, &c., was really detrimental to the original simplicity and beauty of the instrument. The photometer should be placed unboxed in a well-ventilated, darkened room; and every gas company should be furnished with that. A photometer-room was as essential a part of gas apparatus as a purifier, or anything else connected with a properly-furnished gas-works. Also, in the case of a corporation or other public body who might wish to test the gas, especially where penal clauses were concerned, a well-found photometer-room was an absolute necessity. Under these circumstances, it was evident that the boxing-in of photometers might be dispensed with. As Mr. Livesey had said, the discussion was not on standard lights; but still a word on candles might not be out of place. As far as his own experience had gone, he thought the candle had been “more sinned against than sinning.” Although he had frequently tried to get the very extraordinary results which had been recorded by some observers, he had failed to obtain them with an open bar, and in a well-ventilated room. He was far from saying that the candle was an altogether satisfactory standard; but he did not think it was quite as black as it had been painted. He would not trespass further on the time of the meeting, except to urge on all the members the advisability of trying experiments with the most simple apparatus. In the form of photometer as first invented nearly 50 years ago, arrangements were made for reversing the screen at every alternate observation if wished; so that the original inventor did not lose sight of this very important point.

Mr. NORTON H. HUMPHREYS (Salisbury) said that one point which had been clearly brought out in the paper was very important—viz., not only should there be a perfectly steady air supply, but the photometer-room should be maintained at an equal temperature of about 60°. He had used a bar photometer some time ago, and had adopted boxes like the towers which had been mentioned at each end; and, not having a small room, he had put it up in a large one, with a curtain arrangement. By this means, he could draw back the curtain, and keep the bar at the atmospheric temperature; and he found that he obtained much better results than was formerly the case when the photometer stood in a small room, where the temperature would rise. He had both the candle and the gas-burner boxed in all round, with rather larger circular openings at the top, and open at the bottom; and both boxes were kept perfectly cool. It was not only of importance with regard to the candles, but also in the case of the gas, that the air supply should be steady and equal in temperature throughout the experiments. If all these points were observed, which was not difficult, they would not hear so much about the wide differences with candles.

Mr. FRANK MEAD (Sutton) remarked that Mr. Dibdin had made one very pertinent observation. Many members of the Institute were furnished with these closed Evans photometers; and if he understood the observation referred to correctly, the closed photometer with the top on gave 17·1, against 16·2 candles with a standard photometer. When the box covering the top was removed, the test was 17·5 candles, against 15·8 candles with the standard; but when he took away the zinc screen from the box, concordant results were obtained with the Evans photometer and the tower photometer. Now, if by the removal of the box top and the zinc gauze, an Evans photometer would give concordant results with the standard, what could be more simple than

just to lift away the portions he has mentioned of the instruments, instead of having entirely fresh instruments—a serious matter of cost.

Dr. DUPRÉ (London) desired to point out that the original inventor of the photometer under consideration was Bunsen. Bunsen, however, used a photometer on which the two lights to be compared were always on the same side of the disc; and this, it appeared to him, had certain advantages. First of all, they saw with their two eyes, instead of seeing, when looking in the mirror, the two discs with different eyes, which did not always give the same results. Bunsen worked in a dark room; and when he made the experiments which led to the invention, he prepared himself by living for some days in a perfectly dark room. He (Dr. Dupré) could quite imagine, if the photometer was only enclosed in a dark box, and they looked on the discs with different eyes, unless a considerable time was allowed to elapse before the observation was made, it might lead to error; the two eyes being somewhat differently affected by the light on coming from a comparatively light room to the dark box. He should think that the fairest way of testing gas would be some approach to the conditions under which the consumer used it. When a man wished to read by gas, he did not retire into a dark box. It seemed to him that the fairest way to the consumer and to the gas company would be to test the gas in an open room; but the room should be darkened, so that the eye of the observer was at its best for the work, and, if possible, it should be arranged that the disc should be seen with the two eyes simultaneously.

Mr. C. HEISCH (London) said that the paper under discussion was very interesting to him, as he had been working on photometry for nearly 50 years. In the first place, he perfectly agreed with Dr. Dupré that the use of the eye for one side of the disc only was essentially bad. They ought certainly to look at both sides with both eyes; but in an open photometer, this was very easily managed. It was only necessary to retire a sufficient distance from the disc, and both sides practically could be seen at once; for the slightest possible movement of the head was sufficient to show the two sides to both eyes without any trouble. With regard to the question of boxing up the lights, this had been one of the great difficulties ever since the introduction of the Evans photometer. After the passing of the Act of 1860, all the gases supplied to the City were tested by the open-bar photometer at the Jewry Street station. The three gases from the City of London Gas Company, The Gaslight and Coke Company, and the Great Central Company were all led into one room, and tested on the same bar with the same apparatus. This continued until the passing of the Act of 1868; and then the gases from The Gaslight and Coke Company and the City of London Company were transferred to the Evans photometer; but the Great Central Company's gas remained for testing on the open bar. The new system, as far as the gas from the Bow Common works was concerned, began on Lord Mayor's Day, 1880. He was free to confess that, until the Evans photometers were introduced in the City testing-stations, he was not absolutely ignorant of their existence; but pretty nearly so. He had been in the habit of going all about the country testing gas; but never met with one out of the Metropolitan district. They were almost all open bars; and he believed an open bar was the best thing they could possibly use. Free ventilation, both of the candle (or whatever the standard might be) and of the gas was obtained. Two objections to the Evans photometer, besides its want of ventilation, were: (1) They looked at the disc through a pane of glass, which did not increase the facility of accurate reading; and (2) it was a temptation to a man to take a reading when his eyes were not in the best condition. He would sit in a light room, and just go under the hood, and take his observation; but if he waited (say) one or two minutes after getting under the hood, the observation would probably be different. With regard to the Evans photometer, Mr. Dibdin seemed to him to have an idea that it invariably increased the apparent light of the gas, and diminished that of the standard; but he happened to have in use two photometers which had precisely the reverse effect—most distinctly depreciating the quality of the gas to a considerable extent. In order to be at all fair to the companies, he took off the bottom trough in which the cords ran, and sometimes the top cover; and he now obtained from the two photometers very much the same results as he did with an open bar—which was almost invariably from 1 to 1½ candles higher than he could before he took off the bottom. He thought this peculiar effect might be due to that circumstance; but, not being quite certain about it, he only threw

it out as a suggestion. The disc holder in the centre of the photometer happened to fit very close indeed; so that both the heat and the carbonic acid generated principally at the gas end did not find their way beyond it. Therefore, the candles were, comparatively speaking, little affected—there being only a slight rise of temperature, whereas all the carbonic acid was collected on the gas side; and he believed it was this which had the depreciating effect. He mentioned this to show that the Evans photometer did not always work in favour of the gas company. With respect to the much abused candles, he agreed with Mr. King that a large amount of abuse had been wasted on them which they did not deserve. They deserved a good deal, but not to the extent they had received; and he believed much of it was due to the fact that the rule which Mr. King mentioned—of leaving things alone—was not adhered to. They had had limits fixed lately in regard to the burning of candles, which had put it almost beyond the power of the candle manufacturer to make a really good candle. It was all very well to fix a maximum limit as to the amount of sperm which could be burnt, because a candle of that size would not burn more than a certain quantity. It might get rid of it by smoke evaporation, and so on, if it had too big a wick; but the sperm would not be nearly burned. When they fixed a minimum limit, and said the candle should not burn less than 38 grains in ten minutes, it was a different matter. He believed it was of very little importance whether a candle burned 38, 36, or 35 grains, because the sperm was all burnt; and he had himself had—when he had the opportunity of working with gas-holder gas which was not interfered with—instances in which the reading on the photometer varied from 21 candles down to 16; and when they were calculated out to the quantity of sperm burnt, they were within 0.1 of a candle. The other way he could not say the same thing; for if they went up beyond 40 or 41 grains in ten minutes, the sperm was seldom fairly burned, and they would be liable to error. But going downwards, he did not believe there would be any errors, provided they looked well to the shape of the wick. If the wick took a corkscrew shape, or if it stood bolt upright, the candle ought, of course, to be thrown away; but if it burnt steadily with a dry cup, and there was just the proper inclination of the wick to bring the lip of it into the edge of the flame, provided too much sperm was not burnt, he did not think the candle was a bad article after all. They all knew, from the report which he made in conjunction with the late Mr. Hartley, that he was a great believer in the Methven screen, because he considered there were several points about it which made it superior to almost everything else; the principal being that, as the same gas was used for both sides, they were quite sure the lights were the same colour. Anyone who had had much to do with photometry knew that this was a very important point in accurate reading. He did not wish to enter into a discussion of the various standards proposed; but he did strongly object to the introduction of a very large standard of comparison. If they used a 10-candle standard, a difference of 1-10th on the two surfaces of the disc represented only 1-100th of the light on the disc. If, however, they had a 1-candle standard, a difference of 1-10th of a candle represented 1-10th of the whole light on the disc; and he must be a very bad observer who could not see the difference. But to see the difference of 1-100th in the light of 10 candles was by no means so easy; and he had always found that the attempt to use a large standard would upset the observations of three or four accomplished photometrists, which would be absolutely identical when they were using a 1-candle or even a 2-candle standard.

Mr. G. R. HISLOP (Paisley) thought the faults attributed to the Evans photometer were chiefly due to the want of science in its construction. Some years ago he had occasion to purchase an Evans photometer for a room that could not be darkened; and he could not by any means obtain more than 70 to 75 per cent. of the light he should have done from the gas. On the top of the photometer there were two funnels—one at either end; and thinking they were to a great extent the source of the mischief, he removed them. But still he could not obtain a steady flame. He then closed up the opening on top to about a half, by a piece of iron; and even then it did not act properly, until he had pierced a good many holes in the bottom of the box, when he realized results comparable with those from an open photometer. He therefore thought the defects were due to want of taking care to provide against undue air currents. By the means he had explained, he had obtained a steady flame; and the results were raised to what they ought to be.

Mr. J. MILES (Bolton) said that, like Mr. Heisch, he was a great admirer of the Methven screen. He was in the habit of testing by both methods. But invariably with a Methven screen he got superior results (by about 1 to $1\frac{1}{2}$ candles) as compared with the ordinary bar photometer; and he could not find out the reason why this should be so. The greatest possible care was exercised to have the readings alike in every particular; but this result usually occurred. He should like to know if Mr. Heisch could give any explanation as to this, or if the same results had been observed by others.

Mr. A. EDWARDS (Taunton) remarked that he had found the difference was 1 or $1\frac{1}{2}$ candles the other way with the Methven screen. There must certainly be some reason for this variation. On the question of candles he should like to relate a somewhat singular experience that he had recently had.

The PRESIDENT reminded Mr. Edwards that the paper was on photometers.

Mr. EDWARDS said he only wished to mention that, trying two sets of candles—one set being six months old and the other five years old—they gave, on the same photometer, a difference of $1\frac{1}{2}$ candles.

Mr. DIBDIN, in reply, said he was pleased to find that Mr. Livesey entirely agreed with him in condemning the Evans photometer. He was also glad that he pointed out clearly to the meeting that his recommendation of the tower photometer was not unqualified, but that he said advisedly if, after having heard the opinion of some experienced gas engineers who had a decided preference for a closed photometer, they must have a closed photometer, he thought the tower or "Imperial" was by far the best form. In his own work, however, he certainly preferred a simple and open bar, put into a moderately large room free from draughts. He had had considerable experience with such an instrument, which he now found spoken of in the highest terms of praise. Some few years back, it fell to his lot to work with such an instrument in different parts of the Metropolis, and because he packed it up in a box carefully, and had to put it on the top of a cab, it was dubbed a "wheelbarrow" or "peripatetic" photometer; and it was supposed that it could not give accurate results, however it was used. He could not help recalling this little bit of history, when he heard that the simple open bar, used in an open room, was after all looked upon as the best instrument. He found that this form entirely did away with at least 75 per cent. of the objections against candles, because it had been rather a joke among the staff of experienced gas examiners that, when they had had candles as they called them at one of the testing stations, when the Evans or semi-closed form gave results of a very contradictory character, that the cry immediately was: "Send them down, we will use them on the open bar." Then they would put them on the open against other candles. The result would be 16·2, 16·3, 16·4, 16·2; and, changing the candles again, they would be 16·3, 16·5, 16·5, 16·2, 16·4, and so on. They would not get a variation of half a candle when using the same candles which had given 18 or 19 candles in the Evans photometer. They sometimes found 25 per cent. of variation in the legal instrument; but when they used the illegal "wheelbarrow," "travelling," or "peripatetic," or portable photometer, as he preferred to call it, the results were very much more satisfactory. Professor Foster had read a very interesting letter which gave the most unqualified condemnation of the Evans photometer from so eminent an authority as Dr. Letheby; and after that there was not much to be said in favour of the present legal closed test. There had been a most interesting discussion, which it was not necessary to go through in detail; for it was all summed up in an unmitigated condemnation of the Evans form. In one instance, he found that the experience of the staff with which he was associated utterly condemned the Evans photometer, because it so happened with them that when it went wrong, as it commonly did, it made the gas too high, and thus misled the gas engineer as to the value of the gas sent out; because if they returned 18-candle gas for a 3-inch flame, they knew there must be something wrong, and trouble was created in the mind of the engineer who was doing his utmost to perform his duty. On the other hand, he found an eminent authority like Mr. Heisch, who had two Evans photometers which gave results precisely in a contrary direction, obliged to strip them in order to show the gas to be of the quality they believed it was. After that there could be no longer a word said for the use of the Evans photometer; and it was to be hoped that the proper authorities would take cognizance

of these facts, and at once withdraw their sanction from the instrument. Still, some of the highest gas authorities—men who were looked upon in that assembly with great respect, and most deservedly so—did advocate, for their own special reasons, the use of a closed photometer, as against an open one. Therefore, if they meant to have a closed instrument in deference to the opinion of others, let them have the one they had now before them, in the shape of the "tower," which was really a modification after all of the Keates open-bar photometer, simply enclosing the lights with big towers, because he found, after the most careful examination, that it gave perfectly concordant results with those obtained with the open bar. Though, of course, there might be little errors and liabilities to mistake in working a new instrument, still be thought, on further experience, it would be found that the instrument would not militate against the interests of the gas companies, but rather in their favour, by letting them know what was the true value of the gas which they were sending out; and thus enable them to conduct their business in the most business-like way. Under the present system, it was as if a man were to weigh a pound of tea with a lump of clay, which might be 1 lb., 12 oz., or 20 oz. Such was the state of things in which the gas companies were placed, because they did not know what they were measuring with. He asked the co-operation of all the authorities to assist in taking this stigma from the officials who had to do with gas. It was a most painful position; night after night they were compelled by law to commit an entire fraud. He knew the responsibility of such a statement; but it was a fact that, with the full knowledge of the authorities, they were compelled to commit a nightly fraud. They were provided with an instrument which was incorrect, which was known to the authorities to be incorrect; and still they must either report the actual result of the test as made under the Act of Parliament, and the instructions issued by the Gas Referees, and appear as if they did not know their business, because they should have to report such extraordinary results, or they must exercise their discretion as men understanding their business, and report something which they did not find, when working with the official instruments according to the Act. It was not right to ask them to continue in such a position. That was his real object in bringing the question before so intelligent and powerful an association as The Gas Institute.

[Mr. Sugg, who was unable to be present during the reading of this paper, so as to take part in the discussion, has written a letter, which appears in another column to-day, in reference to Mr. Dibdin's conclusions.—ED. J. G. L.]

DIFFERENTIAL CHARGES FOR GAS.

By H. WOODALL, of London.

Had the fortunes of gas companies been placed at the mercy of an evil genius, with power to do his worst by a single Act, I could well imagine his malign influence finding expression in a clause limiting their right to sell gas save at uniform prices throughout their several districts. I feel pretty confident too that, were an effort made to impose such a limitation upon companies, it would arouse the most united and strenuous opposition. Yet, as a matter of fact, one-half at least of all the gas supplied in Great Britain is sold at prices which are uniform over the various areas of supply. How are we to explain the anomaly? Well, no doubt the case was not so anomalous a few years ago, when gas was without a rival; and the language which I have used must be taken as that of one who views the situation from the stand-point of to-day. Still, what we see to-day in the conduct of our business, can scarcely be said to show any sign of change, and is but the natural product of all our yesterdays. The main difference in the position seems to be in this—that yesterday any policy, or no policy, was good enough; whereas to-day it is apparent that, if we must take and hold, it must be in well-fought fields, and that looseness in policy may lead to permanent disaster.

It is not much I am going to recommend in the way of innovation; indeed, I may say scarcely more than has already been done by many. But, simple as my proposals are, I know there will be many among you who will find it hard to accept them, as being at variance with your former practice. Nor can I wonder if such is the case; for, from time immemorial, gas has exercised a wonderful fascination over the minds of men in the direction of conservatism; and, in many instances, it has shown itself to be capable of transforming even the most pronounced of radical free-traders

—whether individuals or communities—into upholders of protection. Many years ago I remember John Bright—that sternest of free-traders—boasting that the town hall at Rochdale had been built out of the profits of the gas-works. That is to say, that the few had been taxed for the advantage of the many, and that trade had been taxed for the relief of property. Manchester—once the centre of liberalism—has always pursued a protectionist policy in regard to gas, and is to-day as hardened as ever in its wrong-doing. Manchester gives place to Birmingham; and straightway the latter falls a prey to the same contradictory folly. Leeds next becomes the centre of radical action; and very nearly succumbed to the same infatuation. But, like “a brand plucked from the burning,” it was rescued; and I trust I may be pardoned for expressing the hope that it may retain its pride of place only so long as its practice in respect to gas is in accord with its professions, in regard to trade and commerce generally. That is to say, so long as gas shall be allowed to go unfettered. For, manifestly, a corporation who charge for gas a price which is in excess of what it can be made and sold for, is differentiating in favour of other illuminants, as by every penny that the gas consumer pays out of his bill towards the reduction of rates, by so much is he contributing towards the extinction of his property in the gas-works; he is sustaining, by a bounty, an industry which could not thrive so well under proper competition, but which, under this class of protection especially, is capable of doing an infinite amount of mischief. What then shall be said of those corporations who, possessing gas-works, are directly subsidizing out of rates installations of the electric light? In one direction, taxing the gas consumer for a costly experiment, and in the other, taking from him the profit which resulted from the supply of important premises. This is surely robbing “Peter to pay Paul” with a vengeance. First they charge an excessive price to cover extravagant public expenditure; then they set up a competitor to some extent out of those misappropriations of profit; and then give to that competitor some of the most profitable business which the gas consumers bought at a high premium, and upon which premium they may have to pay interest in perpetuity! And English gas consumers, who, as everyone knows, have courage enough to seek the bubble reputation in the cannon’s mouth (especially when it is not loaded), cannot produce one man in a hundred to protest against the imposition of such unjust burdens.

In this connection, I will venture to relate a parable. Some years ago my little daughter, then aged four, having strayed away, I went in search of her; and eventually found her in a neighbouring field, milking a cow into a tin can, which another and younger urchin was holding. It was an interesting spectacle for more reasons than one; for something about that cow reminded me of the Manchester gas consumer. She had a vacant look about her; and seemed to be perfectly oblivious of her obligations towards herself or others, and her conduct in allowing her dugs to be wrung by unauthorized persons did not belie her looks. Those seeming innocents quickly developed into “highwaymen”—I mean highways committee men. I need not tell you what they carried away with them; but I can assure you that it had a strong flavour of gas about it. But while I have nothing to say in extenuation of the gas consumer, I must in fairness say this for the cow. There had been an accident at a neighbouring oil-works, in consequence of which the adjacent pastures had been saturated with paraffin. The cow felt that she must eat or die; and so for the nonce “her sense was apoplexied.”

Now, supposing the field to be cleared of the parasitical growths which too often encumber it, have we liberty to deal with our product as wisdom may direct? Not always; for gas is too often forced to compete under straightened conditions, which are inimical to the interests of buyer and seller alike. Almost all companies may charge prices varying with the quantity sold; but some at least are precluded from selling at several prices for several purposes. Thus, you may sell a million feet at a price 50 per cent. under the general price; but half that quantity used differently, might yield a larger amount of profit, and yet you may not sell that, subject to the smallest abatement. Some years ago, having advocated the sale of gas at a low price for purposes other than lighting, I found myself unexpectedly and most completely put out of court, by a clause in an old Act, which stipulated that the price charged to one person for a given quantity should be the price charged to every other person using the same quantity. A reasonable clause enough in the day in which it was framed, when there was no thought of gas being used for motive

purposes, and still less in lieu of smiths’ fires. It is clearly desirable then that, whenever an application to Parliament is necessary, care should be taken to annul all such antiquated restrictions.

Now we will suppose gas free to compete upon its merits in a fair field; and I advance the proposition that, as in all other businesses, profit should be shared between the seller and buyer. I venture also upon another proposition—that, to ignore this principle, must in the long run prove detrimental to the interests of the seller. Hitherto gas-works management has set at defiance every principle of trade. Frequently, it has supported a certain class of consumers at the expense of another class; and very often we have made concessions to the very smallest of our customers in excess of those we have made to our larger. Take, for instance, the case of a company supplying gas at a uniform price, and not charging rent for meters. In such a district a railway company pays £2000 per annum; and the interest on meters need not exceed £20. In the same town 2000 customers might be found whose united consumption would not amount to the sum I have mentioned, but who have entailed an expenditure on meters alone of not less than £1500, interest upon which sum, together with wear and tear, would cost not less than £200. And yet in many quarters we see the railway companies being lost; and efforts being made to make good the situation by advances to cottagers.

Now a central railway station is about the best customer that we can have; and as the special advantages of electric lighting are sacrificed in connection with such premises, we ought the more easily to hold our own. Why are we supplanted? I know that gas can be supplied in certain towns at 1d. per candle per 1000 cubic feet; and I know, too, that, where something approaching this price is being charged, gas occupies the field almost to the entire exclusion of other illuminants. It is patent then that the purveyors of other methods of lighting must ever be greatly indebted to those companies which persist in charging the same price to those out of whom they make profit as to those who involve a loss; and not for worlds would they, at any rate, have the old policy disturbed. That there are many of our customers whom we should be better without financially, I have no doubt whatever. I have in my mind a town in which there are 70,000 consumers, 20,000 of whom do not average more than 10s. per annum, and 100 of whom consume 10 per cent. of the gross supply. The leakage is at the rate of 3000 cubic feet per customer per annum; and, supposing one-half of this to be from the main, and the other from the service, we have to deduct from the 10s. the manufacturing cost of 1500 cubic feet of gas as a first charge against the customer, while, as a matter of course, all other charges—such as cost of service, maintenance and renewal, inspection, collection, &c.—are in excess. All these charges together, worked out as a percentage on the higher class of business to which I have referred, would be inappreciable. Yet in this same town there was one customer, whose account was about £3000 per annum, who applied for an abatement, and could not obtain the smallest concession. He thereupon resolved to make his own gas; and the withdrawal of his custom will entail a loss of at least £1500, which the remaining customers will have to pay. Now, had he received an abatement of 20 per cent. to which on every ground he was entitled, he would have continued to take his supply as before; and the other consumers would still have had £900 of profit out of him, to share amongst themselves. Think what that customer stood for! The gross income from gas in the case of the undertaking to which I refer, divided by the number of consumers, gives less than £3 per customer. It would, therefore, take at least 1000 average consumers to equal this one; while it is certain that 1000 of such customers as are added from year to year would not yield the same profit.

I am afraid that one great cause operating against the adoption of differential charges is the sliding scale, which, designed for the purpose of giving to shareholders a direct participation in all profits as they accrue, may reasonably be regarded as antagonistic to proposals to remove any portion of a company’s business from beyond its influence. But it is already becoming apparent that the sliding scale may become, instead of a reasonable servant, a bad master; while not a few, even amongst its warmest admirers, are of opinion that it should be to some extent restrained. I venture to suggest that the best way to curb it is to remove that class of business which is most in peril out of its reach. Surely it is better to have present dividends (which in all conscience are high enough) assured through long

years, than to exact higher ones, with the inevitable result of alienating the best of your customers, and of leaving to your heirs and successors an attenuated and unstable business. I am glad to note that Mr. Livesey himself is not unfavourable to some interference with the prerogative of his child to pinch, and that he proposes a decremental rate of increase in his power to do harm. For my own part, I think it would be better for all parties were he bound over for a 1000 years. Then we may hope to win back the good friends whom we have lost, and to hold all that we have, by dividing profits in excess of present dividends amongst those who are most entitled to consideration.

I have said before, and I say it again, that, under a system of uniform prices, the largest consumers receive even less consideration than the smallest, for whom we are constantly "trimming" burners, or perhaps providing gas-stoves at unremunerative rents. This anomalous condition can be very simply corrected by a system of discounts. Not on any account would I propose to interfere with any mode of legitimately extending the use of gas amongst the masses; but I do contend that we ought to be just before we are generous, and that to ignore this law will only be to court misfortune.

Discussion.

The PRESIDENT said it appeared to him that this paper went somewhat beyond its title, as he understood it, because Mr. Woodall had touched upon three principal points—first, the undesirability of local authorities making a profit out of gas; secondly (and this was the main object of the paper), he pointed out the desirability in some cases of differential prices; and, lastly, he had made some remarks on the sliding scale. No one was more able to express an opinion on these subjects than Mr. Woodall. At the same time there was another side to each of these questions; and he was sure Mr. Woodall would be pleased if those who entertained different opinions would express them.

Mr. J. P. LEATHER (Burnley) thought that Mr. Woodall was hardly correct in what he said about leakage. Certain towns were professing to sell more gas than they really made; and the unaccounted-for gas was not always leakage, but depended to a great extent—sometimes almost entirely—on the different temperatures at which the gas was measured at the works and at the consumers' meters. It was hardly fair to debit each consumer with this proportion of unaccounted-for gas.

Mr. GEORGE LIVESEY (London) said he was much obliged to Mr. Woodall for bringing forward this paper; but he had expected a much stronger one. Whether Mr. Woodall, by his visit to Australia, had been converted from a lion into a lamb he did not know; but any rate he had shown a great deal of moderation in his views. As far as the paper went, he was prepared to endorse almost everything the author had said. He agreed it was only just that the large consumer should have some allowance made to him; and he had contended for many years that, if the small gas consumer, who paid £2 or £3 per year, was charged the same price per 1000 cubic feet as the man who paid hundreds or thousands of pounds, the large consumer was in fact being charged more for his gas than the small one, simply because it cost less in all the expenses of administration to supply him. There was only one service to look after, one meter to inspect, one account to collect, less trouble for the clerks, and so on; and on this ground alone, the large consumer had a decided claim to an allowance. It was rather difficult to make this adjustment, however; and in some cases it went a great deal too far, and the advantage to the large consumer was much greater than it ought to be. In the case of the South Metropolitan Gas Company, they adopted the rule of allowing a discount of 5 per cent. to the railway companies and public bodies, which satisfied them. In London, and probably in the country, the difficulty of making differential charges was in consequence of the wording of the Acts of Parliament, which compelled them to supply the public lights at the lowest price charged to any private consumer. Now, the public lighting was a series of small consumers, for there was a separate service to each lamp; and therefore a good deal of the argument in favour of giving the large consumer a discount did not apply in dealing with public bodies. If they were to make a very large abatement to railway companies and large consumers, they would have to supply the public lights at the same rate. Their experience was that the 5 per cent. allowance was satisfactory; for there had been no complaints made, and the large consumers seemed to understand that their right to a difference was recognized.

As to the sliding scale, there was really no difficulty whatever. It was within the power of any company under the sliding scale to make differential charges if they pleased, though it was true they could not calculate the dividend on the lower price. If the general price was 3s., although the large consumer was supplied at a cheaper rate, the dividend must be calculated on the 3s. price; and this did no harm. Under the sliding scale, the advantage to the company was no doubt great; but it was also great to the consumer. He was prepared to prove that, taking London at any rate, the price for gas would not be so low by some pence per 1000 cubic feet as it was now, had it not been for the sliding scale. It was an inducement to reduction of price; and, although an advocate for a decremental rate of increase on the sliding scale, he was not an advocate for its abolition. If this were the case, the main inducement to make further reduction of price would be destroyed. Those who had got up to 12 or 13 per cent. should be content to take a diminishing ratio; and instead of taking $\frac{1}{4}$ per cent. for each penny reduction, let them take $\frac{1}{4}$ per cent. for each reduction of twopence. This would be satisfactory all round; and they need not then abolish the sliding scale, which had proved very beneficial, keeping down capital and preventing agitation. They had now been thirteen years without any public outcry against gas companies; and this had never happened before.

Mr. T. NEWBIGGING (Manchester) said he agreed generally with the proposition that the large consumer should have an advantage; but he wished to put this limitation upon the remark—viz., that he should be a consumer all the year round. In this respect he must say a word in favour of the small consumers, who, in many manufacturing towns in Lancashire, were the backbone of the gas undertaking. Although the large consumer burned a great quantity of gas, he only did so during three or four months in the year; and he required to have it within a few hours each day. The consequence was that throughout the summer months a very great proportion of the capital expenditure was unproductive. If it were not for the steady consumption of the small consumers under such circumstances, it would be very difficult indeed to carry on the undertaking, and pay dividends on the heavy capital which had to be expended on increased plant and mains so as to supply the large consumers during a limited portion of the year.

Mr. C. R. MEAD (Sutton) pointed out that the difficulty of supplying large consumers under the Act at a limited price had been overcome in the case of two Acts obtained by companies he was connected with, within the last few years, in this way: The Committee had allowed them a special clause enabling them to supply any consumers at lower rates by having a special agreement in writing. There was a great deal of skirmishing over the clauses; but they got them through.

Mr. LIVESEY asked if they could supply such customers at a less price than the public lamps?

Mr. MEAD: Yes.

Mr. G. SHEPARD PAGE (New York) said the practice in the States with regard to this question might possibly be of interest to the members. One reason for the much greater selling price of gas in the States was the fact that nearly all public lighting had been done by private gas companies; and in making contracts with the city councils, a stipulation was made as to the price at which the gas should be sold. As there were in most places competing companies, there was competition for what was the largest single customer—the street lighting; and this had reduced the cost of public lighting to a figure which represented something like 4s. per 1000 cubic feet, while the price to the private consumer would be 5s. or even 6s.—as, for instance, in Washington, where they carbonized about 40,000 tons of coal per annum, and the price to the general consumer, including the Government, was 5s., while for the city lamps it was 90 cents, or about 3s. 7d. There was but little restriction as to the price to be charged. Gas companies could make contracts with their consumers; and, with the larger consumers, it was a question of buying and selling. As in nearly all matters of business, the wholesale buyer had an advantage over the retail buyer, naturally the larger consumer would get the advantage. In Boston the price to the general consumer was, until the beginning of this year, \$1.40, or about 5s. 7d. Then an opposition Water-Gas Company was established on the usual basis of about \$1 for the capital expended on works, and about \$5 for "watered stock." About the time when the water gas plant was to commence operations, as the water gas advocates and exploiters were not able to induce the

Boston Gaslight Company to see what great benefit they were going to be to the city, they were met with a counter proposition by the Boston Gaslight Company which did not please the water gas men at all. The water gas men were intending to take in certain of the suburban gas companies about Boston, who were selling gas at an average of about 7s.; the Boston price being 5s. 7d. Having secured all these companies, they supposed that the Boston consumer, who was only paying, for his store, shop, or manufactory, \$1.40 per 1000 cubic feet, and living in the suburbs where he was paying 7s., would not object to have the price raised in the city from \$1.40 to \$1.50. That was the plan of the Water Gas Company; and, as he had said, it was met by a counter proposition, on the part of Mr. Greenhough and his associates on the Board of the Gaslight Company, in the form of an announcement that, on Jan. 1, 1888, the price of gas to the general consumer would be \$1.30. They had visited all the largest consumers in the city, the large percentage of whom were under contracts for five years at 4s.; and very little stock had since been sold in the Water Gas Company. Nearly \$2,000,000, or about £400,000, had been expended by the very benevolent gentlemen who came largely from Philadelphia to Boston; but not a foot of gas had been sent out from that station. He thought therefore they would draw the conclusion that the differential price of gas paid the Boston Gas Company.

Mr. WOODALL, replying on the discussion, said he was glad to find there were so many agreed with the proposals he had made. Mr. Leather had touched on the question of leakage, and disputed his way of dealing with the subject; but he could not alter the fact that, taking towns generally, and dividing the leakage over the number of consumers, it came to about 3000 feet per consumer per annum. He did not care what the leakage was as the percentage of the quantity of gas made; it would generally work out something like a given rate per mile. But, of course, it would vary per customer, according as to whether the customers were large consumers or not, and the character of the district. In thickly populated towns, however, it was generally about 3000 feet per customer. He was very pleased to find that Mr. Livesey approved generally of his proposals. He had felt for a long time past that London was under great disabilities at the present time, in consequence of the very active competition all round, both on the part of electric light and oil; but Mr. Livesey's strong objection was that they could not make a concession to large consumers which would be profitable without making it also to the public lighting authorities. On looking into the matter, however, there was not so much in it as might at first sight appear. Although he was strongly opposed to letting public authorities have gas except at the extreme price, still they had the power in their hands, and it could not be taken from them; and they would exact the very best terms they could on behalf of their constituents. Taking the public lighting account generally, it rarely exceeded 7 per cent. of the gross sales; and supposing an abatement were made of 20 per cent. from this 7 per cent., it only amounted to 1 per cent. on the gross income, which was not very much. Therefore, for the sake of retaining the largest and best consumers, he should not hesitate to give this consideration to the public authorities. Mr. Livesey, of course, supported the sliding scale; and he (Mr. Woodall) did not raise any objection to its continuance. He only urged that there should be a limit to the dividends which should be paid under it; and suggested that, instead of adding to the dividend, they should do that which would make their dividends quite secure, by giving a consideration to the large consumers in future. If the accruing profits of gas companies were to be given to the consumers from year to year, they might continue in perpetuity the 13 per cent. of to-day, and would probably be able to pay even greater dividends if disposed after a time. Mr. Newbigging had raised a very important point, which he had always felt was a difficult one in connection with differential prices. There was no doubt about it that the publican, the theatre, and the railway company were amongst the best of their consumers, because they consumed gas regularly throughout the year, and for the greatest number of hours. The mill-owner, on the other hand, demanded the largest amount of gas over a limited number of hours; and as the works and mains had to be sufficiently large to meet the greatest demand, capital expenditure was extravagant in relation to his supply. However, if the discussion had realized nothing else, it had brought out the very important point that Mr. Mead raised—that it was possible to obtain power from Parliament to make special agreements in writing with

customers. This was the great thing to be desired by gas companies—that they should be in a position to do that in their own interest and in the interest of consumers, which almost every other trading body was able to do.

Essays, Commentaries, and Reviews.

GAS AND WATER COMPANIES IN THE STOCK MARKET.

(FOR STOCK AND SHARE LIST, see p. 38.)

BUSINESS on the Stock Exchange during the past week has been decidedly fair, though none of the markets have been extremely active. A favourable influence was exerted by the pacific aspect of affairs on the Continent—exhibiting a market contrast to the state of almost general apprehension which prevailed not so long ago. The Money Market has been very easy; the requirements for the settlement, and the close of the half year, producing no stringency. The tendency has thus been in favour of better prices all round; the Foreign Market having perhaps the best of it. The Gas Department has been extremely quiet; but all stocks have been firm, with the single exception of Commercial old. A parcel of this stock being offered on Monday, and realizing only 265 as the best bid, brought the quotation down. There were no further transactions in it during the week; and we do not expect to see any more allowed to go at such a figure. It will not bear comparison with the prices of Gaslight "A" and South Metropolitan "A," to which the stock is in no way inferior. To bring Commercial to pay a fraction over 5 per cent., ought to be good business. Gaslight "A" has not been extensively dealt in; but it has grown steadily stronger every day. The last price marked, 252, was the best of the week—against 248½, the best of the previous week. A few transactions have been marked in the debenture and 10 per cent. preferences, at good figures. The 4½ per cent. debenture stock is quoted 5 better than the similar stock of the Commercial; and again it is hard to imagine why. South Metropolitan have been inactive; two or three deals in the "B," at middle figures, being the sum total. Imperial Continental has been steady; maintaining its advance of the previous week, but not improving upon it. Other undertakings offer nothing for remark, except Bahia, which has advanced 1, and Continental Union, which is ½ better. The Water Companies have been very inactive; and show few changes, except on deduction of dividends. Southwark, ordinary, however, recovered the 1 it had dropped the week before. East London was weaker, and receded 1½. The daily operations were: On Monday the opening showed a favourable tendency in all departments. Business in Gas was only moderate; but every stock dealt in was very firm, except Commercial old, which receded 3½. Water was quite featureless. There was a shade more activity in Gas on Tuesday, and at very fair figures. Buyers of Gaslight "A" made the price 1 higher. Water again offered nothing to remark. Gas was quieter on Wednesday, but prices were disposed to rise. Gaslight "A" improved 2. Water was very quiet and unchanged. Business in Gas continued very restricted on Thursday, but with undiminished firmness. Bahia rose 1; and Continental Union original was ½ better. In Water there were a couple of transactions in New River; but nothing else was touched. Business in Gas on Friday was at about the level of the previous day. Prices were still disposed to rise, but quotations were unaltered. One transaction in Southwark ordinary (which rose 1) was all the business in Water; but East London fell 1½. On Saturday there were only two transactions marked in Gas, and none in Water; and all quotations closed without any change.

ELECTRIC LIGHTING MEMORANDA.

THE ELECTRIC LIGHTING ACT AMENDMENT BILL PASSED—THE ELECTRIC LIGHTING INSTALLATION AT LEAMINGTON—ELECTRIC LIGHT TROUBLES IN THE UNITED STATES.

THE Electric Lighting Act Amendment Bill has become law; having received the Royal Assent on the 28th ult. It now remains to be seen whether it will bring all or any of the benefits ascribed to it in advance by its promoters. We believe, as we have held all along, that the Act will be useless as a means of reviving the electric lighting industry, which suffers under financial and economic, rather than legal disabilities. Curiously enough, a criticism of the measure in *Industries* (probably written by an electrician, and meant as a reproach to Mr. Chamberlain's Act) confirms this view. The critic is complaining bitterly of the restriction of the purchase-money of an electric lighting concern to the actual value of the plant, &c.; and he remarks: "Where improvement is so rapid as in electric light machinery, the market value of the plant a few years after its erection is liable to be considerably below its first cost; and therefore the recompense represented by the purchase-money would not have been equivalent to the outlay, even after a few years. A glance at the price lists published by the leading dynamo makers five years ago and those published now will make this evident. The price of low-tension dynamos, suitable for central station work, shortly after the passing of the Act, averaged over £1 per lamp; now it is barely half that amount. It is evident that had a company started some five years ago, they would have had to purchase machines at the high figure of £1 per lamp, and would have had to sell them, under the compulsory purchase clause, at the lapse of 21 years, to the local authorities at less than 10s. a lamp. This would have represented a dead loss of one-half of their original outlay." The writer cannot see that this

is one of the greatest recommendations of Mr. Chamberlain's Act, regarded from the point of view of the local authorities. Why should £1 of public money go for 10s. worth of plant, merely because a company were foolish enough to buy dynamos when they were dear, instead of waiting until they became cheap? According to the plea of our contemporary, the high prices of electric lighting plant five years ago would be perpetuated at the public cost. The Electric Lighting Act stopped this injustice; and now the electricians have obtained all the relief, in the matter of length of tether, they wanted—or at least all they could expect to get. Even *Industries* tells them they ought to be satisfied with the new Act. But shall we see a revival of electric lighting projects for the coming season, in consequence of this alteration of the law? It is possible, but very unlikely, except as a merely speculative venture to form a basis for stock-jobbing manipulations.

It appears from a statement that has been published that the electric lighting plant at Leamington is not being utilized as speedily as its projectors expected. The plant actually in position comprises four Chamberlain-Hookham shunt-wound dynamos, all of 800 lights capacity; but two of them are sufficient to supply the 1100 lamps actually in nightly use. A small current for day service is supplied by an accumulator, as the engines are only driven at night. The distribution was first on the Hopkinson-Edison three-wire system; but, "owing to the great complication entailed by this system," it has been abandoned for the ordinary two-wire system. This does not say much for Dr. Hopkinson's great invention. A commissioner of *Industries*, who made a special inspection of the Leamington installation with a view to ascertain the facts, confesses that the street lighting is not altogether a success. He speaks well, however, of the private lighting. The private supply is generally measured by a meter of Mr. Hookham's invention, which is like a small dynamo, and is revolved by a percentage of the current required for lighting. The supply is charged for at the rate of 8d. per unit when the consumption is under 40 units per quarter; between 41 and 150 units, the charge is 6d. per unit; and beyond this quantity, it is 4d. This is equivalent to 16-candle gas at from 6s. 8d. to 3s. 4d. per 1000 cubic feet. The price of gas at Leamington is 2s. 7d. per 1000 cubic feet. Altogether, the special correspondent of *Industries* thinks that the Leamington electric lighting experiment is "a modest, yet fairly successful attempt to supply a public want." It is to be hoped the proprietors are satisfied with their venture.

A correspondent of the *Electrical Engineer* states that New England and the Eastern States have experienced the epidemic "now quite general" of trouble with electric light wires. The Edison station at Fall River was recently burnt down—of course, on a most awkward night for the subscribers. In Halifax, Nova Scotia, a servant of the Electric Light Company was killed by touching a wire on a pole in the street; another workman in the employ of the Company having shared the same fate a week previously. The fact appears to be that the distributing plant of the speculative companies who have been "running" the electric light in American towns during the past two or three years has become very much the worse for wear, and both companies and the public are now feeling the disadvantages of make-shift fittings. If the electrical speculators are wise, and the business of electric lighting is worth saving, they will take steps for putting matters right before a wave of popular discontent sweeps them away. As it is, they can hardly live for each other. Competition is very keen; and they declare that the intense rivalry for business under which they live is extracting every cent of profit from the work. So that, according to common report, the life of an electric lighting speculator in the United States is not altogether a happy one.

PRESENTATION BY MR. G. GARNETT OF A MACE TO THE CORPORATION OF RYDE.—Last Wednesday the mace which, as stated in the *JOURNAL* a few weeks ago, Mr. G. Garnett, M. Inst. C.E., the Engineer and Secretary of the Ryde Gas Company, had expressed his intention of providing, at his own expense, to complete the insignia of office of the Mayor, was duly handed over to his Worship (Mr. R. Colenutt) and the members of the Corporation in the Town Hall last Wednesday. Mr. Garnett made the presentation; and in doing so remarked that if they had one-tenth of the pleasure in accepting the offering at his hands which he felt at being its donor, he should be abundantly gratified and repaid. Having described the design of the mace, he expressed his satisfaction at the manner in which the work had been carried out by the manufacturer (Mr. Thurlow), and concluded by wishing the Mayor and Corporation, and all present, health and happiness for many years to come. In the evening Mr. Garnett was entertained at a complimentary banquet by the Mayor and Corporation. Alluding to this event, and to Mr. Garnett's connection with Ryde, the *Isle of Wight County Press* last Saturday said: "For thirty years this respected citizen has lived and worked in our midst; and in many ways the town and its people are the better for his presence amongst us. He has been closely identified with the municipal history of the town. Having been one of the promoters of its incorporation, he has now most generously completed the equipment of its governing body with due insignia of authority. It is a satisfaction to know that, as a result of this last mark of his devotion to the interests of the town of his adoption, his name will be handed down with honour to future generations. That he may long be a living example of the success which attends self-deny and persevering labour and of noble purpose is, we are sure, the earnest hope of his numerous friends."

COMPLETION OF THE EDINBURGH AND LEITH GAS-WORKS TRANSFER.

By the agreement with the Edinburgh and Leith Gas Company which was executed on Friday last, the transfer of the undertakings of the Edinburgh and the Edinburgh and Leith Gas Companies to the Corporations of these two places is virtually secured. The controversy has been the occasion of much discussion locally, on account of an opposition which was very vehement in utterance, but was in reality powerless either with the community or with the Legislature. To sum up the history of the negotiations, it may be said that the Joint Committee of the Corporations which took charge of the subject had presented to them at the outset one of the most difficult problems which any Committee similarly situated ever had to solve. They had either to take over the undertaking of the Edinburgh Company on the spur of the moment and with scanty information, or to see the possibility of the community acquiring the gas supply of the district receding into a very dim and distant future. They accomplished the first portion of their task speedily and with credit. They then set themselves to the acquisition of the Edinburgh and Leith Company's undertaking. This should have been easy of accomplishment, seeing that there was plenty of time in which to carry on the negotiations with the Company; but, unfortunately—acting either from advice which was not the best, or from preconceived notions—the Committee created difficulties for themselves, which retarded a settlement until about the last possible moment. Now that the bargain has been completed, it is satisfactory to know that the agreements with both Companies are sufficiently favourable to preclude the possibility of regret on the part of the shareholders at parting with their property, and that at the same time the communities may reasonably expect to reap a handsome profit out of the gas supply. The Edinburgh Company receives £20,000 a year in annuities, and other considerations which will raise the annual charge on their behalf to about £21,000. The Leith Company receives £14,000 in annuities, and other sums which raise the total annual charge on their behalf to £18,809. These two sums together amount to £39,809. This year the Edinburgh Company has earned a profit of £37,000, and the Leith Company one of nearly £27,000—together, £64,000. The results this year may be regarded as so exceptional that they can scarcely be founded on; but the amalgamated undertaking may be relied upon to produce at least £45,000 of annual profit, which will leave upwards of £5000 to be applied (after providing for sinking and reserve funds) either in the reduction of the price of gas or in the redemption of annuities. Taking into account the natural increase in the gas consumption, it is consequently evident that the Corporations have, on their part, effected a very safe bargain with the Gas Companies.

Turning to inquire how the matter stands with the Companies, one is met at the outset with the peculiarity of the position of the Edinburgh Company. The record of this Company is probably unsurpassed by that of any other in the United Kingdom. So well managed has it been, that upon a capital of £200,000 not only has a dividend at the rate of 10 per cent. been regularly paid, but the works have been largely extended out of revenue; and about three years ago accumulated profits to the amount of £45,000 were distributed by way of bonus among the shareholders. A further sum, stated a year ago at £63,000, awaits distribution; and, in addition, the shareholders will soon have divided among them the sum of £27,000, which the Corporations pay as grassum, and a further sum estimated at £30,000, the cost of stores to be paid for by the Corporations—together, £120,000. By the change from dividend to annuities, nearly two years' payments will be made to shareholders during the next twelvemonth; the sum receivable being £37,965 as compared with (at most) £25,000, if no change had been made. Adding the sum to be distributed from revenue during the year to the above-mentioned £120,000, it is brought out that in the course of one year the shareholders will, upon £200,000, receive a return of £157,965. If to this, again, is added the £45,000 distributed three years ago, the magnificent result is arrived at that about the whole capital of the Company will have been returned to the shareholders, and that they are to draw perpetual annuities at the rate of 10 per cent. upon this capital so returned. In the case of the Leith Company the capital is £150,000. The Company have never paid a bonus, but have expended a large proportion of their profits in the extension and renewal of works. The shareholders will be entitled to divide among them, after the 1st of August next, £11,000 of grassum received from the Corporations; the value of stores, £20,000; and their reserve fund of £21,723—together, a sum of £57,723. Adding in their case the amounts of dividend and annuity payable within the next twelvemonth, their total receipts for the year will be £82,410, or more than half their capital.

It will be observed that the shareholders of the Leith Company, though the annual charge upon the community on their account is relatively higher than that on account of the Edinburgh Company, do not occupy so favourable a position in the matter of the distribution of assets as do the shareholders of the Edinburgh Company. This is accounted for by the fact of their business being smaller (only about half that of the Edinburgh), and their large expenditure on works and plant. The increased charge in their case is on account of their capability to go on for a number of years without renewal or extension; and on the same account they have received terms, when compared with the Edinburgh Company, relatively higher than the size of their business warranted—the equity of this lying in the fact that the Company might have reasonably expected

to realize a larger return from their works for some years than they have been accustomed to earn. The two undertakings will be carried on together; and on that footing, the cost per 1000 cubic feet works out at nearly 8d., which compares well with the Birmingham transfer, where the cost was 9d. per 1000 cubic feet. On both sides, therefore, there is matter for sincere congratulation at the result of the negotiations.

A PRESIDENTIAL ADDRESS AND A HISTORIC RELIC.

THE Société Technique de l'Industrie du Gaz en France were fortunate in their President for the past year—M. Albert Ellissen—if only on account of the highly interesting address which he had provided for them, a translation of which was given in the JOURNAL last week. We have not the slightest doubt that the President for the current year—M. Cornuault—will present the world with an interesting address in his turn; but it will not be easy to surpass M. Ellissen's production. A striking proof of that unity of professions in different countries which is brought about by the modern development of technical journalism, is to be found in the fact that the Inaugural Addresses of the last presidents of the British and French Gas Engineers' Associations both contain references to the presidential utterances of foreign compeers. Mr. Gandon quoted M. Alavoine; and M. Ellissen referred to Mr. Foulis. Nay, even more strikingly, M. Ellissen had recourse to Mr. Thomas Duxbury to enforce his own observations upon the extent of ground that yet awaits cultivation by suppliers of gas. It is impossible to overrate the importance of this reciprocity in technical study. Compilers of valuable statistics, and authors of good papers on gas supply, have therein a guarantee that they address a larger audience than that to which they appear to speak; and the reflection should brace them to worthier efforts. An original-minded and able gas engineer attains a world-wide reputation, while perchance he thinks himself known only in a corner of the country to which he belongs; and there is not a grain of valuable seed in paper or address or technical article that is not caught up and spread abroad in the principal languages of the world. If it appears to fall into unthankful soil at first, there is no telling where a fruitful idea may eventually germinate.

M. Ellissen addressed a body of men whose occupation and interest is like that of British gas managers, but whose circumstances are radically different. Gas supply in France, and in the countries influenced by French ideas in this respect, is a very different thing to the same business as carried on in England. It is established on a narrower basis, and presents the peculiar characteristics of licensed undertakings. It has a rigidity, derived from the general concession system, which is not found in the same degree in any other business of the kind in the world. It is often asserted of gas engineering that it is not too progressive, even in countries where unrestricted competition or direct inducement of another kind exists to favour development of processes. What, then, is to be said of it when the financial conditions of its existence positively discourage change of any kind? Having regard to their circumstances, and the fact that the system of concessions has the effect of tabooing many subjects on which their compeers of other nations are free to exercise their wits, the anxiety displayed by the members of the Société Technique for professional intercourse and instruction is most creditable to them.

It is possible to lose sight of much of the limitation that oppresses gas engineering in France in perusing the observations of M. Ellissen upon the present and past of gas supply in England and on the Continent of Europe. His comparative table of the gas consumption of London and some of the principal towns of the Continent is very instructive, and calculated to benefit continental gas engineers. It appears from this statement that the gas consumption of London per head of population is very greatly in excess of that of any other town in the list; Paris and Brussels coming next, with Berlin some way behind. We do not know how this list was prepared, and in particular it is rather difficult to accurately collate gas consumption with population statistics in the case of London; but to whatever modification such considerations might lead in regard to the units of M. Ellissen's calculations, they are probably trustworthy in the main. Compared solely with regard to consumption of gas per head of the population, it would therefore appear at first sight that continental capitals have a good deal of leeway to make up before they can stand alongside of London in this respect; but we cannot make the comparison on this basis alone. The price of gas enters too seriously into the question to be ignored, even for a moment; and having regard to this consideration, the point of saturation of a continental community for gas may be really more nearly approached than would appear from a simple statement of bulk of gas sold. The practical importance of this consideration is very easily appreciated. If there are two places equally circumstanced in every respect, the fact of the gas consumption in one being double what it is in the other might be regarded as an incentive to the administration of the gas undertaking in the latter place to take steps for diminishing the difference. This they might do by enlightening the people as to the advantages of gas, and offering a variety of inducements to its extended use. If, on the other hand, the price of gas in one town is only one-half what it is the other, the point of saturation, beyond which no progress in extending the consumption is to be expected, would be reached much sooner in the dearer district. Speaking generally, the foregoing remarks express the whole philosophy of gas supply, as it is understood and expounded in our columns.

The most universally interesting portion of M. Ellissen's address is the historical part of it. The author is led to regard vehicles carrying lights in towns as part of the street-lighting arrangements; for he says that if the street lighting by other means were perfect, there would be no need for carriage-lamps. *Ergo*, a carriage-lamp is a street-lighting arrangement. There something in this argument; but it will not bear much strain. Suffices, however, to take M. Ellissen back to the consideration of times when the only public street-lamps used in Paris were of a perambulatory character; and it is rather striking to learn that the first contractor for lighting the streets of the capital of France and the centre of European culture ruined himself by the enterprise. Many others have since discovered that there is little or no profit in public lighting. It is very instructive to observe how readily people were to ascribe finality to the—as we now see them—imperfect methods of street lighting adopted in Paris during the last century. Are we, as M. Ellissen hints, too prone to commit the same fault? It is possible; but we cannot quite agree to the proposition that the unexplored resources of physical science are as boundless now as they were a hundred years ago, even though men may not be any better or more humble in their estimates of their own knowledge.

We have some hesitation in accepting M. Ellissen's view of the work of Philippe Lebon, who is described in the address as having had great difficulty with his "marvellous invention" in "dethroning" the Argand lamp. The English view of the matter is that if it had rested with Lebon to dethrone it, the oil lamp would have been paramount still. It is a bit of national pride, which we should be loth to call Chauvinism, that credits Lebon with being the inventor of gas lighting, since it is certain that he was never a maker of gas in the sense that Murdoch was; but the matter is not worth arguing about. The French have quite made up their minds that Philippe Lebon was the inventor of illuminating gas, and we have decided to ascribe the honour to Murdoch. It is a small point, though not without its significance; but we ask how is it, if the inventor of gas was a Frenchman, that so many English words are used in the nomenclature of gas making? Why is there no French equivalent for coke? However, there is no advantage in disputing the point. The French have put up a statue to Lebon, while we have not, up to the present time, done as much for Murdoch; and so we must give them credit for stronger feeling on the subject.

While referring to the early days of gas lighting, it will be a convenient opportunity for mentioning the curious relic of this time in the shape of the prospectus of Mr. Robert Roberts, proprietor of the Oswestry Gas-Works in the year 1821, a reprint of which will be found in another column. Here we have a most interesting reminder of the conditions of gas lighting before the general introduction of meters; and the facts offer a strange similitude to the circumstances of electric lighting at the present day. It must be confessed, however, that the enterprising Mr. Roberts, of Oswestry, was very particular as to the terms upon which he supplied his gas. Some of his subscribers were only allowed to burn gas until nine o'clock, and there was an increasing charge for keeping the burners alight for every hour later until midnight. What a premium was here upon early and regular hours for retiring! He graciously informs his customers that he will not be particular to a quarter of an hour, and will allow the lights throughout the town to be kept on until eleven o'clock on Wednesday and Saturday evenings; but he tells everybody that unless his regulations are conscientiously followed, he will refuse to supply. What a picture do these regulations afford of the way in which the gas maker was at the mercy of the renter, save only for the right of the former to make domiciliary visits at all hours. One's respect for the meter is sensibly increased after thus being brought face to face with the difficulties inherent to any pure rental system. It will be noticed that the astute Mr. Roberts claimed his rents in advance, and was not unfavourable to weekly payments. He strongly advised the use of a glass "consumer," the reasons for which are very innocently given. He particularly objected to tampering with the burners with a view to getting a better light; but how inferior the other means of lighting available at that day must have been, is shown by the fact that as much as a guinea a year would be paid for the use from sunset till nine o'clock of a miserable little rat-tail gas-jet $3\frac{1}{2}$ inches long, probably of two or three candle power at the utmost, and occasionally redolent of sulphur to a degree that would baffle the glass "consumer" to conceal. The gas was pretty good in those days, so far as mere illuminating power was concerned; for it was made at a comparatively low heat, in iron retorts, without mechanical exhaust, and purified by wet lime. The expenses of distribution, however, and the cost of everything required in the works, were very high. Even a brass cock was a philosophical instrument. We recommend this "relic" to future compilers of presidential addresses, as it suggests many more reflections than we can find space for here.

As M. Ellissen remarks, fashion in the matter of artificial lighting has changed since the days when a single $3\frac{1}{2}$ -inch jet was considered a sufficient light for a room. A saloon that was regarded in 1780 as lit up *a giorno* with 1800 wax candles was not considered too brilliant with 8000 probably better candles a century later. An incident such as this is rightly regarded by M. Ellissen as a sign of the times. He at least is not disposed to claim finality too soon. The greater the quantity, and the higher the quality of the light that can be provided for the world's use, the better in his opinion. There is room for all. Gas competed in Oswestry

67 years ago with candles, and underbid the chandler even when selling at rentals equivalent to a price of 15s. per 1000 cubic feet. It was a better and a cheaper light; and if it holds its own anywhere, it must be for the same recommendations. Gas has improved since 1821; and so have candles. Electricity may improve during the next 60 years; and so will gas. "The thing that hath been is the thing that shall be;" and there is nothing in this reflection to make the friends of gas lighting afraid.

THE PAST YEAR'S WORK UNDER THE ALKALI ACT.

THE Twenty-fourth Annual Report of the Chief Inspector under the Alkali, &c., Works Regulation Act, 1881 (Mr. A. E. Fletcher), was issued last week. It embraces the labours of the Chief Inspector and his colleagues during the past year; and as these gentlemen have the supervision of those gas-works in which the manufacture of sulphate of ammonia is carried on, the publication has special interest for our readers. The number of works in England and Ireland now registered under the Act is 927; being an increase of 17 over the number in the previous year. Adding to these the 139 works registered in Scotland (which are separately reported upon), the total in the United Kingdom at the close of last year was 1066. In most of these works several processes are carried on, each of which comes under inspection; and therefore may be regarded in the light of distinct works. Of these processes there were 1245 at the close of 1887; being an increase of 37 over 1886. Adding the 198 in Scotland, we have 1443 as the total for the United Kingdom in 1887, as against 1395 in the previous year.

Taking, first of all, the figures relating to England and Ireland, we find that there were last year 26 processes under inspection connected with the treatment of "gas liquor," as it is styled in the report, and 311 connected with the manufacture of sulphate and muriate of ammonia. The places where the various processes are carried on received 4383 visits last year, and 4402 tests were made. If on the occasion of an inspector's visit the work is found to be in an unsatisfactory condition, the object kept in view is not the obtaining of evidence to support a prosecution, but the speedy improvement of the work. To this end the visits are repeated; and an examination is made of the escaping gases, so as to indicate the source of the difficulty, and assist in finding means for its removal. Usually such action on the part of the inspector—though, Mr. Fletcher states, it is not always welcome at the time—is ultimately acknowledged with satisfaction by the manufacturer; and the expense that may have been incurred in the work is felt in the end to have been money well spent. Mr. Fletcher gives, in tabular form, particulars as to the quantity of deleterious gases emitted in each district under supervision last year, together with the corresponding figures for the two immediately preceding years. The acid gases (stated as SO₂, and expressed in parts per cubic foot) escaping from the sulphuric acid chambers were as follows:—1885, 1.52 grains; 1886, 1.40 grains; 1887, 1.50 grains. The acidity of chimney gases, expressed in a similar way, was: 1885, 0.67 grain; 1886, 0.77 grain; 1887, 0.74 grain. Mr. Fletcher states that the average result of all the tests made throughout the country is very uniform year by year. The amount of hydrochloric acid escaping has for the last three years been 0.1 grain in each cubic foot of chimney smoke. This is exactly half the amount given as the limit in the Alkali Act. The quantity of the same acid gas measured in relation to the production has gradually been diminished, till now it stands at a little less than 2 per cent. of it; the limit given in the Act being 5 per cent. The amount of sulphurous and other acid gases escaping from the sulphuric acid chambers is now, on an average, equal to 1½ grains of sulphuric anhydride; the limit given in the Act being 4 grains. There were four prosecutions under the Act last year; three being for carrying on unregistered works. In these cases penalties of £3, £10, and £18 (the two former with costs) were inflicted; and one firm was fined £20 and costs for neglecting to use the best practicable means for preventing the escape of noxious gases. In Scotland, as stated, the number of works under inspection last year was 139; being one more than in the previous year. The number of separate processes was 198, of which 65 related to the manufacture of sulphate and muriate of ammonia. There were 508 visits paid by the inspectors during the year; and 261 analyses made of escaping gases. From the statement of the total quantity of the principal materials used or produced in the works inspected during the year, it appears that 36,658 tons of sulphate of ammonia were made—5711 tons from ammoniacal liquor, 4842 tons from iron-furnace gases, and 21,098 tons from shale-works.

Taking first the section of the report dealing with alkali works, Mr. Fletcher refers to the struggle that has for several years been carried on between the Leblanc process for the manufacture of soda and the ammonia-soda process of more recent introduction. The result of this contest is awaited with keen interest both by chemists and by those who are commercially concerned therein; the Leblanc process having stood its ground so long, and been more successful than all those processes which have hitherto been brought into competition with it. As bearing on the future position of the alkali trade, Mr. Fletcher notices the interesting process lately elaborated by Messrs. Chance Bros., alkali manufacturers, at Oldbury, for saving the whole of the sulphur which has till now been thrown away in the alkali waste, so well known for its noxious qualities. On this ground the improvement promises, he thinks, to be one of great public advantage, by utilizing a substance which was expensive to dispose of, which caused a nuisance where it was deposited, and was liable to give rise to a sulphurous and malodorous

drainage continually. The quantity of this material now annually produced is 1,500,000 tons; and as the alkali trade is confined to a few districts, the waste is there deposited in enormous quantities. At Widnes alone these deposits cover 450 acres, and contain about 8,000,000 tons of the material. An addition of 1000 tons is made to them every day. The amount of sulphur contained in it is 15 per cent.; and of this Messrs. Chance recover very nearly the whole. The residue deprived of its sulphur is mainly composed of carbonate of lime, and is free from smell. It will probably find an application in the manufacture of cement and otherwise. Another new process now actively prosecuted at Widnes promises, with other changes in the soda manufacture, the accomplishment of the same end—the recovery of the whole of the sulphur in the alkali waste. The arrangement is proposed by Messrs. Parnell and Simpson, and is a combination of the ammonia-soda process with that of Leblanc. It is already at work on a large scale; but sufficient time has not yet elapsed for the commercial results to be known. The promoters, however, say that the process has entirely fulfilled their expectations, and that it is an established success.

Turning to the portion of the report dealing generally with the manufacture of sulphate of ammonia, we find that the total quantity produced in the United Kingdom last year was 113,896 tons (having a market value of £1,253,000), against 106,610 tons in 1886. Of the former total, gas-works produced 85,022 tons; iron-works, 5098 tons; shale-works, 21,098 tons; and coke and carbonizing works, 2678 tons. The figures for the preceding year were: 82,480 tons, 3950 tons, 18,080 tons, and 2100 tons respectively. The important increase to be observed in each case is due, Mr. Fletcher tells us, to the gradual development of trade, and more skilful manufacture, rather than to any new methods of manufacture. There is reason, however, to expect that a large addition may take place from the coke and carbonizing works, and, in particular, from the forms of coke-ovens and gas-producers introduced by Messrs. Brunner, Mond, and Co. In his previous report, the Chief Inspector gave an account of results achieved during six months' continuous working. The quantity of ammonia collected from the coal treated was three or four times greater than that usually produced in gas-works, though even then only half of the possible ammonia had been obtained. The amount of sulphate of ammonia gained was 66 lbs. per ton of slack, the value of which was nearly sufficient to pay for all the coal used in districts where this is cheap. Since that time the apparatus has been in constant use, dealing with 15 to 16 tons of fuel daily. The proprietors are, we learn, so satisfied with the results obtained, that they have put down a largely increased plant—one sufficient to consume from 200 to 240 tons of fuel, and to produce from 6 to 7 tons of sulphate of ammonia every 24 hours. Mr. Fletcher thinks there is good reason to expect that this will be the prelude to considerable changes in our method of burning coal, resulting in a largely increased yield of ammonia.

The Chief Inspector passes on to deal with the subject of smoke-prevention—a matter touched upon in his two preceding reports; and mentions approvingly the efforts now being made by Messrs. Brunner, Mond, and Co., to substitute gaseous for solid fuel. In this connection allusion is made to Mr. Hargreaves's thermo-motor (which was noticed in the JOURNAL in the early part of the present year), with which either liquid fuel or coal may be used. With this engine, an energy of 40-horse power can be maintained with the expenditure of 2 gallons of coal tar or 45 lbs. of coal per hour. Seeing, then, that by the application of further skill in the ordinary use of coal as a fuel, by the adoption of one of the many successful smoke-preventing appliances now available, the emission of black smoke may be avoided, and many collateral advantages obtained, Mr. Fletcher thinks it may be said that the time has come when the law prohibiting the emission of black smoke should be made applicable in all cases, and should be strictly enforced.

Mr. Fletcher closes his report with a few general observations on the Act under which his operations are conducted. He points out that the scope of the original Act, passed in 1863, was extended in 1881 so as to embrace a number of works not contemplated at the earlier date; among them being those in which gas liquor is made use of in any manufacturing process. He thinks it would now be well to include all those processes in which sulphuretted hydrogen is liable to be given off, as well as some others which he specifically mentions. He considers that manufacturers should be compelled to use the "best practicable means" for preventing the emission of noxious gases from their works. Such a provision would, he says, "prove an elastic bond ever tightening as chemical science advanced and placed greater facilities in the hands of the manufacturer." If this view of the subject was adopted, a comprehensive measure for controlling the escape of noxious gases might, he thinks, be so framed as to depend mainly on two clauses—the first defining a noxious gas as one which gives cause for complaint, or referring to a schedule in which such gases are named; the second, declaring that the best practicable means must be adopted to prevent the emission of such a gas. While offering these suggestions for purging the Act of certain of its blemishes, Mr. Fletcher refers to the excellent results that have been obtained by virtue of the measure as it stands. An inspection that was at first dreaded by the manufacturers as an infringement of their rights—an unwelcome intrusion into the secrecy of their operations—has, he says, been acknowledged by them as an aid in the management of their works, assisting them to maintain a standard of manipulation previously thought to be unattainable, and establishing a system of measurement and analysis of waste

gases which has in some cases brought about their profitable employment. In all the works which have come within the scope of the Act, a great and continued advance has been made in the discovery and use of methods for more completely preventing the escape of noxious gases.

Following the Chief Inspector's report are the reports of the District Inspectors, some of which are noticed at length to-day (p. 31), and the remainder will be referred to next week.

THE LONDON COAL AND WINE DUTIES BILL.—Mr. W. H. Smith, in reply to a letter from Conservative members of Parliament for Metropolitan constituencies, says that in the present condition of business it is impossible for him to hold out hope that an early day can be found for the consideration of the Coal and Wine Duties Bill.

THE ELECTRIC LIGHTING EXPERIMENT AT LEAMINGTON.—The Lighting of the Leamington Parade with incandescent electric lamps is still far from being satisfactory; and it is reported that experiments are about to be made with arc lights. Before any extensive changes are made, however, the Corporation will probably be approached in the hope that the town will bear a portion of the expense.

MILL LIGHTING BY GAS.—The Hurst Mill Company, near Ashton, employing about 6000 hands, have hitherto obtained the supply of gas for their two mills from separate works for each mill, both, however, being under the management of Mr. W. Taylor. The Company have decided on discontinuing this arrangement, and having only one large works, furnished with all the most modern appliances for the economical manufacture of gas. Acting on the advice of Mr. Taylor, the work of reconstruction has been entrusted to Messrs. R. Dempster and Sons, Limited, of Elland; the contract (which comprises everything but gasholders) to be completed by the end of September next.

PRESENTATION TO MADAME ALTING-MEES.—Our readers may remember that on the occasion of the gas exhibition held under the auspices of the Jersey Gas Company in April last, lectures on cookery were given by Madame Alting-Mees, and were largely patronized. A desire was then expressed by a number of ladies to take advantage of Madame Alting-Mees' presence in the island to improve their knowledge of cookery. As, however, her engagements did not allow of this being done at that time, a course of lessons was arranged for a future occasion. These have lately been delivered, and have been attended with great success. In order to show their appreciation of Madame Alting-Mees' kindness and courtesy, as well as in recognition of the benefits they have derived from her tuition, the ladies who formed the class have presented her with a pair of handsome Sax-China candelabra.

THE PRICE OF GAS AT LIEGE.—In reference to the paragraph in last week's JOURNAL in which it was stated that for the future the price for day gas is to be 10c., and for night gas 15c. per cubic metre, the Managing Director of the Liège Gas Company (M. Fayn) informs us that this does not quite correctly represent the conditions under which gas will be supplied in the town as from the 16th inst. There is to be no difference whatever in the price of day and night gas. The Gas Company sell the gas in bulk, at the rate of 11c. per cubic metre, or about 2s. 5½d. per 1000 cubic feet, to the municipal authorities, who retail it at 15c. for lighting, and 10c. for cooking, heating, and motive power; thus making from lighting gas a profit of 4c. per cubic metre, out of which they allow the Company 1c. on account of the gas used for other than illuminating purposes. Whether the gas employed for cooking, warming, &c., is consumed by day or by night, the price will be invariably the same—10c. per cubic metre. M. Fayn adds that there is no town in the Continent in which the price of gas, for whatever purpose required, will be so low as in Liège, when the new tariff comes into operation. The town authorities pay the Company at the rate of 15c. per cubic metre—the price charged to private consumers—for the gas burned in the public lamps.

PRESENTATIONS TO MR. F. W. STEVENSON.—Last Thursday evening the workmen employed by the Chester United Gas Company emphasized the friendly relations which have always subsisted between them and the Engineer and Manager (Mr. F. W. Stevenson), by presenting him with a testimonial, on his leaving the Company's service to assume the duties of Engineer of the Sheffield United Gas Company. The testimonial consisted of a portrait of Mr. Stevenson, a cigarette-maker, a meerscham cigarette-holder, and a silver match-box (suitably inscribed); the whole being the gift of the workmen. The presentation was made by Mr. H. Thomas, the oldest *employé* in the Company's service, who spoke in terms of praise of Mr. Stevenson's efforts to improving the works, as well as to lighten the labour of the men and ameliorate their condition generally. He expressed their united hope that Mr. Stevenson would be successful in his new undertaking, and their best wishes for himself and Mrs. Stevenson. In acknowledging the gifts, Mr. Stevenson thanked the donors for their kindness, and said he should always associate the picture with pleasant thoughts of the *employés* of the Chester Gas Company, whom he wished, in return, long life, health, and happiness. He then introduced to the men his successor, Mr. Robert Hunter. Mr. Stevenson has also been presented with a standard barometer by the Secretary and office staff; and a flattering resolution passed by the Directors of the Company, has also been conveyed to him. It may be truly said that Mr. Stevenson will take with him from Chester the heartiest good wishes of all with whom he has been associated there.

Notes.

THE TESTING OF PORTLAND CEMENT.

Mr. Henry Faija, M. Inst. C.E., has read, before the American Society of Civil Engineers, a paper on cement testing, in which he defined the object of testing cement to be the determination of its constructive value; while the necessities of a test are that it should be expeditious, complete, and reliable. The prime object of the paper was to support the recommendation previously made by a Committee of the Society in favour of the establishment of a uniform system of cement testing. According to Mr. Faija, the value of a cement may be determined by its fineness, and also by its tensile strength at two dates. The greater or less increase in strength between the two dates defines the growth, and determines approximately the ultimate strength to be expected from it. In practice, a test at three days and another at seven days from gauging enables a sufficiently accurate determination to be arrived at. The greater the increase in strength shown between these two dates, the longer it may be expected that the cement will continue to acquire strength, and the greater the ultimate strength obtained. The actual strength demanded of a sample, and whether it is to be quick or slow setting, must be determined by the special requirements of the work in which it is intended to be used. Quick-setting cements, as a rule, attain their greatest strength in about six months. After then there seems to be a falling off in tenacity; but to what cause this is due has yet to be discussed, as, in Mr. Faija's opinion, there is no apparent reason, theoretical or practical, why a strength once attained should be partially lost. The proposed adhesive test is, Mr. Faija declares, unquestionably uncertain and untrustworthy. The adhesion of a cement to any material depends as much on the nature of the other material as on the cement; and even where seemingly similar surfaces are secured, it is impossible to be sure that there may not exist slight differences which will affect the results obtained. The same objection applies to the sand test, which has the additional disadvantage that a considerably greater amount of skill is required to gauge a sand briquette than to gauge one of neat cement. With regard to the fineness of cement, Mr. Faija thinks that a residue of 10 per cent. on a sieve of 2500 holes to the square inch is as much as can be expected of any manufacturer, unless an additional price is paid for extra grinding. The most important point, however, in the first determination of the quality of a cement is the absence of cracking or blowing. This fault is due to excess of lime, and is fatal to the soundness of a cement which exhibits it. To test for this fault, Mr. Faija uses a steaming apparatus of his own devising, in which thin pats of neat gauged cement are exposed to vapour at a temperature of 110° Fahr. The pats are left in this atmosphere overnight; and if they are perfectly sound in the morning, the cement is regarded as a safe one to use.

A MAGNESIUM POWDER LAMP.

A continuous magnesium lamp, designed to burn magnesium metallic ribbon, was described in a "Note" appearing in the JOURNAL for the 22nd ult. (p. 910). Another method of obtaining a continuous light from burning magnesium has been invented, by Dr. H. G. Piffard, whereby the metal is burnt in the form of powder. The primary object of the lamp is to furnish a light for photographic purposes. A continuous current of compressed air or oxygen is made to blow a jet of very finely powdered magnesium in an even and thin layer into an alcohol flame; thus producing an enormous magnesium flame of high actinic power. Oxygen is preferred for this purpose, as the mixture of this gas with the metallic particles aids their rapid combustion. In Dr. Piffard's lamp the supply of powdered metal and the blast are so conveniently disposed that the flame is produced regularly so long as the supply of powder lasts. For photographic purposes, of course, the light is not usually required to be of long duration; and a cylinder of compressed oxygen, such as is furnished for the production of the lime-light, is sufficient. No particulars of cost are given; but it is evident that this must be a very expensive way of getting a light. At the same time, the fact that the power of the lamp may be varied through very wide limits, by increasing or diminishing the supply of metallic powder and oxygen, may render it useful for special purposes.

A FLAMELESS EXPLOSIVE.

Many uses in coal mining and in demolitions in places permeated with an inflammable atmosphere, might be found for an explosive which will do its work without igniting gas. Such a preparation has apparently been found in the explosive known as Flameless Securite, made by the Flameless Explosives Company, of 35, New Broad Street, London. Tests of this compound have been made by independent experimentalists during the past few months, which are claimed to have established the fact that Flameless Securite, when fired in a mixture of inflammable gases, will not cause them to explode. Securite is described as a nitrated hydrocarbon in combination with certain oxidizing agents; and the flamelessness of the combustion of this mixture is due to the addition of a proportion of a certain organic salt. In one set of experiments, the Securite was fired by electricity in a wrought-iron cylinder containing a highly explosive mixture of coal gas and air. Sixteen experiments were made with this and other explosives, in order to obtain comparative results; and in no instance did the Securite communicate ignition to the gaseous mixture in which it was exploded. Even in the case of a dynamite cartridge, which was

rendered flameless by the addition of some of the organic salt, no explosion of gas occurred when the dynamite was fired in it. In some cases the cartridge of Securite was surrounded by coal dust; and in all cases the top of the cartridge was open to the gaseous mixture. In the other series of experiments, Mr. Rhodes, of the Aldwarke Collieries, used the apparatus employed by him for testing safety lamps. It consisted of an iron cylinder with an arrangement whereby a highly explosive mixture of coal gas and air was made to travel through it at a velocity of about 6 feet per second. Coal dust could also be carried through the cylinder with the gaseous mixture. A large number of experiments were conducted with Flameless Securite and other explosives under varying conditions, with the effect of confirming the results obtained in the first series of experiments. If these experimental results are borne out in practical working, the employment of Securite may be a means of saving much labour and risk in breaking up *in situ* heavy castings forming portions of old gasholder tanks, &c., which require to be handled in a dangerous atmosphere.

REFLECTORS FOR DISTRIBUTING LIGHT.—Writing on this subject to the Editor of *Industries*, Mr. Alex. P. Trotter says: "With lamps, or groups of lamps, placed at a distance apart equal to their height above the ground, the maximum illumination is $1 + \frac{1}{2}$ the sum of \cos^2 of the angles whose tangents are 1, 2, 3, 4, &c. = 1.976. The minimum illumination is equal to $2 \cos^2$ of the angles whose tangents are 0.5, 1.5, 2.5, 3.5, &c. = 1.91. The greatest variation is, therefore, about $3\frac{1}{2}$ per cent. In a room 80ft. by 40ft. by 28ft. high, with five clusters of lights, the variation would be inappreciable to the most skilled photometrist; especially when the distribution would be assisted by the reflection from the walls. For street lighting, however, such reflectors should be of material service. The London gas-lamps are generally 12 feet high, and 66 feet apart; the distance being five-and-a-half times the height. The variation under these circumstances is very considerable; the illumination at a point on the ground midway between the lamps is about one-thirteenth of the illumination which would be found below the lamp, if it cast no shadow." Mr. Trotter, who has for many years made a study of this subject, promises to send shortly some notes on the distribution of illumination, and the geometrical design of reflectors for street lighting, &c.

WOODEN WATER-PIPES.—All of the earlier water companies in America, like the New River Company in London, used mains of wood, constructed out of what are known as pump-logs, or timber bored from end to end, and pointed at one end so as to fit into the counter-sink at the end of the next log; the space between the two being caulked with oakum. It is known that these pump-logs have certainly lasted nearly a century in some places, although, of course, they are not to be compared with cast-iron pipes used for such purposes. In some portions of the western part of the United States, they are using large water-mains built of staves, made up similarly to a wooden trunk sometimes used to furnish a supply of water to turbines; and it is found (*Engineering* says) that they answer their purpose very well for light pressures. The present water supply of Tokio, Japan, is by the wooden water-pipe system which has been in existence upwards of 200 years, furnishing at present a daily supply of from 25 to 30 million gallons. There are several types of water-pipes in use, the principal class being built up with planks, square, and secured together by frames surrounding them at close intervals. The pipes less than 6 inches in diameter consist of bored logs; and somewhat larger ones are made by placing on the top of the log, a cap, in which a very large groove has been cut. Square boxes are employed in various places to regulate the uniformity of the flow of the water, which is rather rapid, for the purpose of preventing aquatic growth. The water is not delivered to the houses, but into reservoirs nearly 15,000 in number on the sides of the streets.

THE DANGERS OF ELECTRIC LIGHTING.—A correspondent in Calcutta has kindly forwarded a cutting from a local paper giving the following particulars as to a curious fatality which occurred in that city in connection with an electric light installation. The facts came out in the course of an inquiry held by the City Coroner (Dr. E. W. Chambers), concerning the death of two coolies who died from inhaling nitric acid gas from a number of electric batteries, which they, with 18 others, were carrying at a wedding procession. It was shown that Messrs. Mookerjee Bros. were engaged to arrange a display of electric lighting while the procession was moving from Nintollah Street to a house near Chitpore Road. For this purpose the apparatus for the light itself was placed on a platform carried by 10 coolies, while on another platform there were 80 battery cells, carried by 20 coolies, 10 in front and 10 behind. The latter, inhaling the fumes of the poisonous gas from the cells, commenced to cough violently, and eventually, on arriving at Chitpore Road, they put the platform down on the road, and refused to proceed any further. Some Baboos obtained the assistance of the police who were accompanying the procession, and induced the men to carry the platform to the house not far off. Two of the men died from the effects of the poisonous gas which they had inhaled, while five or six more were in the hospital a number of days. The jury returned a verdict that the deceased met their death by inhaling nitric acid gas, through sufficient care not being taken by the contractors for supplying the electric light. After the verdict, the jury desired that a representation should be made to the police authorities that proper regulations should be made for electric light processions, and precautions taken to prevent such occurrences,

Technical Record.

A RELIC OF THE EARLY DAYS OF GAS SUPPLY.

An esteemed correspondent has kindly forwarded to us, for use in the JOURNAL, the following interesting document, illustrating the conditions under which gas was supplied in the year 1821:—

OSWESTRY GAS LIGHTS.
ROBERT ROBERTS

BEGS to present to the notice of the inhabitants of Oswestry the following Scale of Charges, per annum, for Burners of Various Sizes, calculated for Lighting, to the Hours mentioned:—

Description of Burners.	From Sunset till 9 o'clock.	Ditto till* 10 o'clock.	Ditto till* 11 o'clock.	Ditto till* 12 o'clock.	Height of Flame.
	£ s. d.	£ s. d.	£ s. d.	£ s. d.	Inches.
One single jet	1 1 0	1 5 0	1 10 0	1 15 0	3½
Two single jets	1 16 0	2 0 0	2 8 0	2 16 0	3
Three single jets	2 14 0	3 0 0	3 15 0	4 10 0	3
Cockspur of three jets . .	2 2 0	2 8 0	2 17 0	3 6 0	2½
Argand, No. 1	2 14 0	3 0 0	3 15 0	4 10 0	2½
Do. No. 2	3 6 0	3 16 0	4 14 0	5 12 0	2
Do. No. 3	3 18 0	4 10 0	5 10 0	6 10 0	2
Batwing	2 14 0	3 0 0	3 15 0	4 10 0	2½

* The last column contains the height which the Flame issuing from the respective Burners will not be suffered to exceed.
** These Burners consume 2, 3, and 4 Cube Feet of Gas per Hour, which, at 15s. per 1000f is equivalent to Candles at 3½d. per lb.!!

RULES.

The above Rents to be paid in advance, quarterly or weekly; and no person can be allowed to change his burners but at Midsummer and Christmas, when a written notice must be delivered to the Proprietor, stating the alteration.

Persons who wish to take the light, may apply to Robert Roberts, by whom their names will be entered numerically in a book, and branch pipes laid in rotation. The Proprietor only contracts to fix the pipes just within the house, and to supply the light when the interior is fitted up and made air-tight, which must be done by each individual.

No extra charge will be made, if the light be extinguished in a quarter of an hour after the time contracted for; and on Wednesday and Saturday evenings the Proprietor will allow burning till eleven o'clock.

In no case can any person be supplied with gas without a glass over the burner, as three or four times the quantity of gas is consumed, accompanied with an extremely offensive odour, when this rule is departed from. The Proprietor recommends the use of the straight chimney glasses, in which the gas burns with a much steadier light than in any others. If too large a flame is attempted to be produced, the illuminating power is but little, if at all increased, whilst the light is much injured both in purity and brilliancy, as a quantity of gas passes off unconsumed, to the loss of the concern, and without benefit to the consumer.

The Proprietor begs to state, that he shall expect to have a free and uninterrupted right of access, by himself or servants, to the places where the lights may be used, for the purpose of inspecting the same occasionally, and superintending the observance of these rules. The interior fittings to be done by the Proprietor only, and paid for on completion of the work.

All persons desirous of being supplied with the light will be required to take it for twelve months certain.

The Proprietor is inclined to grant every indulgence to those who take the gas; but he must, at the same time, claim a corresponding disposition on the part of consumers, both as it respects the regulation of the lights, and the time to which they respectively contract to burn them. If he does not meet with this disposition, he must, in justice to the town, refuse to supply those who depart from the regulations here laid down. And he has further to observe, that a violation of these rules will subject the parties to forfeiture of their rent advanced, and deprivation of the light.

October 4, 1821.

On the back of the preceding document was written the agreement entered into between the "proprietor of the gas lights" and the consumer, who, in the present case, was a medical man. The "proprietor" agreed to fix up and complete in the consumer's shop a "certain pipe, with the necessary appendages thereto belonging, so as to convey the gas therein for his use," and also to allow him to use the gas till ten o'clock each night, for one year, as well as to "burn the gas at any time during the night should his profession or business require a light during the said term"—the consumer, of course, "avoiding wilful waste." For the foregoing the consumer agreed to pay "the full sum of eight pounds and ten shillings" at the expiration of the term specified.

The annual "northern district" meeting of the Association of Municipal and Sanitary Engineers and Surveyors was held last Saturday week at Carlisle, under the presidency of Mr. J. Gordon, of Leicester. The members were met at the Council Chamber by the Mayor and other members of the Corporation; and under the guidance of Mr. H. U. McKie, the City Surveyor, and Mr. J. Hepworth, the Gas and Water Engineer, they visited several places of professional interest in the city. In the course of the proceedings, Mr. Hepworth read a paper on the Carlisle Public Baths, erected in 1833-4, at a cost of £7000.

WESTERN (U.S.A.) GAS ASSOCIATION.

The Annual Meeting of this Association was held at Chicago on May 9, 10, and 11; and a full report of the proceedings—which were under the presidency of Mr. EMERSON M'MILLIN, of Columbus—has since appeared in the *American Gaslight Journal*.

The PRESIDENT commenced his address by referring to the progress of events in the gas industry. Gas managers' views, he said, had been broadened; and the policy of gas companies generally had been liberalized. After passing in review the subjects of the papers to be submitted to the meeting, he gave the results of a question circular addressed to over 200 representative gas companies in the United States and Canada, with a view of obtaining information as to the present status of the lighting business. Unfortunately, only about one-half responded; and these did not fully answer the inquiries. It appears, however, that on the whole the demand for gas is increasing. Some 22 per cent. of the companies are supplying arc lights, and several are launching out into the incandescent electric light system. In most cases there were arc, and in a less number incandescent electric lights to compete with. Speaking generally, the use of gas-stoves was increasing, but this could not be said of gas-engines. Much difference of opinion existed as to the advisability of gas companies entering the electric light business; and a number of reductions in the price of gas had been made the last few months. He gathered that the gas business was in a prosperous and increasing condition; many companies securing an additional demand by encouraging the use of gas-stoves. Also that a great change had taken place in the views respecting the electric light; 25 per cent. of the gas companies were now actually working it, and more than 50 per cent. believed in the desirability of doing so. The demand for electric light, both arc and incandescent, was rapidly increasing. In referring to the demand for cheap gas, he compared the continual reductions that were being made in the price of gas with the treatment accorded to consumers by water companies; and this notwithstanding the fact that the gas undertakings mostly belonged to private individuals working for profit, whilst generally water-works were the property of the public, and were presumably worked for their benefit. Increased consumption had had a great deal to do with bringing about the reductions in price; and it appeared to him that the time was now at hand when an enormous increase could be secured, by furnishing gas at a price that would admit of its general use as fuel. It could hardly be expected that illuminating gas could be supplied at such a low figure; but if the incandescent gas-burners now being introduced were made a practical success, then a non-luminous gas could be sold at a very cheap rate. In converting coal into gas, there need not be a loss of more than one-third of the total heating power; and in burning the gas the loss need not exceed one-sixth. So that, by means of gasification, one-half of the heating power of the coal could be practically utilized. When coal was used direct, not more than 10 per cent. of it was turned to account. Therefore there was a large margin on which to base profits, apart from the cleanliness, convenience, and other advantages of gaseous fuel. In families, the substitution of gas for coal would enable one servant to be dispensed with, and thus effect a large saving; and the consumer could well afford to pay 50 to 100 per cent. more for his fuel gas than his coal cost him. Allusion was next made to the work of the State Gas Commissioners in Massachusetts, which seemed to have given general satisfaction both to the gas companies and to the public. The publication of the accounts had done no harm; and in effect the Commissioners protected existing companies from competition, for few communities would care for the inconveniences of a second gas undertaking, when convinced that the established one was working as cheaply as possible, and only paying a fair dividend on an honest capital. The Commissioners' report showed that the total capital stock of gas undertakings in Massachusetts was £2,400,000; and it was interesting to notice that they were assessed for taxation on a basis of more than £2,600,000. The total taxation was rather over 5d. per 1000 cubic feet sold; and some people asserted that gas could be sold for a less sum than the charge for taxes in Massachusetts. After noticing the advantage afforded by these statistics to managers of gas-works, the President concluded by referring to several matters of purely local interest.

A report from the Committee appointed at the last meeting for the purpose of considering the advisability of forming a Gas Institute was presented by Mr. F. Egner. The Committee sent out nearly 1000 circulars, enclosing stamped addressed envelopes. Only 130 replies had been received; and they therefore concluded that the idea of establishing a Gas Institute was not practicable.

Mr. F. EGNER, of St. Louis, Mo., read a paper on "The Purification of Illuminating Gas in Closed Vessels." After some preliminary observations, he proceeded to give an account of the Claus process, and also of that patented by Mr. W. Young, of Clippens. He next read a letter from Mr. F. Arding, the Secretary of the Ammonia Gas Purifying and Alkali Company, which set forth that the cost of a Claus plant for dealing with 2 million cubic feet per diem would be £8000; that the total working expenses, including royalty, might be estimated at 6d. per ton of coal; and that the receipts for liquor, sulphur, and sulpho-cyanides would be 1s. 7½d. per ton of coal. There would be a net profit of 1s. 1½d. per ton; no risk of nuisance or danger in opening purifiers; and the liquor would be obtained in the form of carbonate, and could therefore be safely converted into sulphate in open saturators. Mr. Egner remarked that the first cost of the apparatus would be double that of ordinary lime or oxide

purifiers; but that existing scrubbers, &c., could be utilized, which would diminish the first expense.

In the discussion, Mr. Faben said he had succeeded in purifying in closed vessels to some extent by admitting a small percentage of air at the purifier inlet. In the summer he passed more than 10 million cubic feet of gas without changing the boxes; but he did not do so well in winter, having to make a change (say) every 2 million cubic feet. He had no hesitation in recommending others to try the experiment. The difference in the illuminating power of the gas was not noticeable. If anything, there was some improvement; but if the air supply was increased to any degree, there was a depreciation of illuminating power. He more frequently had to change his purifiers on account of back pressure than because of impurities passing. Mr. King thought it was difficult to regulate the air in exact proportion to the make of gas. Mr. Lansden had tried revivifying the oxide by forcing a current of air through the box, but was unfortunate enough to work the fan too fast, creating such heat that the oxide was fused and converted into black oxide. Mr. Shreve had tried air revivification with success.

Mr. WALTON CLARK, of Kansas City, Mo., contributed a paper on "Fuel Gas." He began by asking the question, "What is the mixture of gases best adapted to meet the wants of the probable patrons of the companies we represent?" Large consumers could manufacture for themselves; so that the managers of gas-works had to consider the wants of housekeepers and small manufacturers. The objects to be sought for were a maximum of heating effect, distributed at a minimum pressure through mains of a minimum size. Hence the specific gravity of the gas should be as low, and its calorific value as high, as was consistent with economical production. It should yield the highest possible flame temperature, as it might be wanted for incandescent light and power. Therefore it should be composed of combustible gases only; and should be free from sulphur and other impurities. He thought that these conditions would be met by a purified mixture of coal and water gases, in about the proportions in which they were produced from bituminous coal; and that this mixture could be sold at a price which would commend itself to the consumer. Such a gas could not be produced so cheaply, either as regards bulk or heating power, as one containing a large proportion of nitrogen; but from its general applicability, its lower specific gravity, and higher flame temperature, he believed it was more economical to produce and distribute, and much better adapted to meet various wants, than any mixture containing a large proportion of producer gas. A pure fuel gas was limited to hydrogen, carbonic oxide, and hydrocarbons; the other substances were merely diluents. A ton (2000 lbs.) of average bituminous coal had a heating power of about 27 million units. In conversion into gas, a large part of this heat was lost; the actual loss varying according to the kind of gas made.

Assuming a ton of coal to be converted into coal gas in the usual way, the tar used to heat the retorts, and the surplus coke used for the manufacture of water gas, the author showed that the resulting mixture would be 39,000 cubic feet of fuel gas (specific gravity 507), having a heating power of 377 units per cubic foot, and a flame temperature of 4480° Fahr. if burnt with 20 per cent. excess of air. The total heat units would be 14,710,000 per ton of coal. If one-third of the coke was converted into producer gas, and the remainder into water gas, the mixture from one ton of coal would be 66,350 cubic feet (specific gravity 751), having a heating power of 232 units per cubic foot, or a total of 15,411,000 units per ton of coal. The flame temperature, estimated as before, would be 4048° Fahr. The loss of heat would be 45.4 per cent. in the first case; and 43 per cent. in the second. Comparing the two mixtures, it would be seen that, in order to secure another 2½ per cent. of the total heat, the volume was increased 70 per cent., and the flame temperature reduced from 4480° to 4048°. For these reasons, he objected to the admixture of producer gas. It would necessitate the storing and producing plant being 60 per cent. larger in capacity, even without considering the difference in the specific gravity of the mixtures, which would make the comparison still less favourable to the producer gases.

Continuing, the author said that M. Claudel had shown that, in the most efficient way of heating apartments, only 13 per cent. of the heat generated from coal was utilized; and therefore 10 per cent. would be a very liberal estimate for ordinary purposes. But a gas-fire was much more economical in respect to the utilization of heat. The efficiency of gas might safely be taken at 50 per cent. Applying this to the above data, it would appear that a ton of coal, burnt directly, only yielded an efficiency of 2,700,000 units; but if converted into coal and water gas, 7,355,000 units could be obtained from it. Therefore the gas from a ton of coal was equal to 2.7 tons of raw coal as used for domestic heating. In regard to power, the author estimated that a ton of coal converted into gas and used in a gas-engine was equal to 1.83 tons of coal burned under a steam-boiler. The introduction of the Welsbach incandescent burner showed how this gas could be used as an illuminant; and perhaps might settle the question of how to supply fuel and illuminating gas through one set of mains. The writer next went into some calculations, in order to estimate the requirements for fuel gas in a city of (say) 150,000 inhabitants; arriving at the conclusion that the annual quantity of coal carbonized would be 106,000 tons. The demand for heating purposes would, of course, only arise at one season of the year; but for power and domestic use, it would be fairly constant all the year round. The maximum quantity sent out would be about 20 million cubic feet per day; and looking at the sudden variations in demand according to change of weather, the storage capacity should not be less

than half this quantity. In conclusion, the opinion was expressed that the solution of the fuel gas problem was to be found in the perfection of an apparatus for distilling coal, and also gasifying the residual coke in the same vessel.

In commencing the discussion, Mr. Loomis insisted upon the extreme importance of selling fuel gas cheaply. He was interested with Professor Lowe in his series of experiments at Lynn, Mass., where fuel gas was being sold at 2s. 1d. per 1000 cubic feet. At that price it was cheaper than coal for cooking and motive power; but dearer than coal for heating. They found that the gas must be sold at 1s. per 1000 cubic feet in order to secure general custom for it. Even at that price it would still be dearer than coal for some purposes. Where coal was 20s. to 25s. per ton, fuel gas at 1s. per 1000 feet was cheaper than coal for accomplishing the entire work of a house—he was speaking of plain water gas, without admixture either of coal or producer gas. Extensive experiments had been carried on in a large Ohio factory, with the result that gas at 1s. 3d. per 1000 feet was found to be cheaper than coal or coke; and therefore, for general purposes a good fuel gas equal to water gas must be offered at 1s. per 1000 feet. He agreed that the water gas might be mixed with coal gas, by which its calorific value would be increased, and it would also be odorized; but he contended that the mixture should be prepared entirely at one operation, in one generator. The producer gas generated in heating up should be used for firing boilers or metallurgical work. He believed that gas companies should not make illuminating gas only, but also fuel gas; though he did not consider that fuel gas, incandescent burners, and the electric light were going to do all the business—there would still be a demand for illuminating gas. He contended that every gas company should not only make illuminating and fuel gas, but they should also use the waste gases for generating the electric light. In any town there were waste gases enough at the gas-works to supply all the electric light that would be needed. He could make from soft coal 40,000 to 45,000 cubic feet of water gas, and also sufficient producer gas to generate 250-horse power for one hour, which would furnish 25 arc lights for ten hours. As yet he had not measured the producer gas; but his process had been tested side by side with a Siemens, and with a Wellman producer for heating steel. Besides producing the water gas, his apparatus heated as much steel by means of the producer gas from it as the other producers did from the full ton of coal. There was no waste whatever. The whole of the coal was gasified, except the ash. He estimated the heating value of his gas at 350 units per cubic foot, and thought that a gas of 300 unit quality could be profitably made and sold at 1s. per 1000 feet. It would not do to use first-class coal, but the cheapest kind obtainable. He was now able to run his water-gas apparatus without any clinking. Mr. Egner said he had been working an apparatus of his own invention at St. Louis for two years, which would make fuel gas, water gas, or producer gas as required, and use either cannel or any kind of slack. Mr. Zimmermann observed that he was now making a mixed gas in a single vessel, as suggested in the paper. The best result he could secure, however, was 35,000 cubic feet of water gas per ton of coal; and he doubted if anyone else had done more in regular working. He had obtained as much as 70,000 feet of mixed fuel gas per ton. As to the producer gases being available in addition, he wished to say that all the heat was required to make the gas and raise the steam. Not only was it necessary to burn all the producer gas, but also to absorb the heat from the waste gases, if extraneous sources of heat were to be dispensed with. The 35,000 cubic feet were obtained when using hot fuel; and the use of cold fuel reduced the yield to the extent of 2000 feet or so. As to using slack, there was very little advantage, unless it could be worked with perfect ease; as, when making gas at the rate of 50,000 feet or so per ton, the cost of coal was insignificant. The President pointed out some differences in Mr. Clark's data, and these he had used on previous occasions. Mr. Clark took the calorific value of marsh gas at 21,343 units; but he (the President) put it at about 26,383 units. The reason of this was that Mr. Clark took the results of experiments on the actual gas; but he took the value of the carbon and hydrogen contained in the gas. He stated that 150,000 cubic feet of producer gas or 50,000 cubic feet of water gas weighed one ton; and after allowing for ash, &c., the smallest quantity of coal that would produce these quantities was 2888 lbs., and in practice more than 4000 lbs. would be required for their production. Mr. Clark, in reply, said that although he agreed that the coal and the water gas might be produced in one vessel, still he thought the coal gas should be handled separately. If it was passed through a bed of incandescent fuel, it would practically be converted into water gas. The mixture of gases he proposed, having a calorific value of 377 units per cubic foot, could not be sold at 1s. per 1000 cubic feet with coal at 16s. 8d. per ton, as it would cost more than 10d. per 1000 feet to make. He considered the use of slack in large quantities for the manufacture of fuel gas would lead to an increase in its price. The use of hot fuel would certainly lead to better results; and he reckoned the fuel account might be reduced by this means to as low as 42 lbs. of coal per 1000 cubic feet of water gas made. With regard to the President's remarks, it would be found, after deducting 13 per cent. for ash, that the analysis quoted in his present communication, and which was accepted by the President in his paper last October, showed a yield of 95 cubic feet of producer gas per pound of coal.

NEXT Saturday the Association of Public Sanitary Inspectors will pay a visit to Croydon to inspect, among other things, the Corporation Water-Works, the Beddington Sewage Farm, &c.

Register of Patents.

GAS MOTORS.—Bull and Co., H.C., Limited, of the Poultry, London No. 10,202; July 21, 1887. [8d.]

In the motor constructed according to this invention, the gas is exploded in one end of the cylinder, and at the other end steam is used; and it is also proposed to use compressed air in combination with the steam. The air is previously superheated, and both the air and steam are used expansively.

The explosive end of the cylinder is fitted with an inner or supplementary piston, which derives its movement from a cam or equivalent device on the main shaft. The purpose of this piston is to remove the products of combustion, and to draw in a fresh charge of gas and air during a portion of the return stroke of the main piston. This charge is preferably compressed previous to explosion during the remainder of the return stroke. By this arrangement, the cylinder is only partly filled with an explosive mixture; and the explosive gases are worked to a greater degree of expansion—thereby reducing their pressure and temperature at the exhaust; so that a greater amount of work is obtained from the explosive gases, which is an important feature in the economy of fuel in such motors. It will also be observed that, by this arrangement, an explosion may be obtained at every revolution of the engine. The inner piston is not quite so large as the cylinder, and begins its return stroke—which is effected by the cam before mentioned—a little before the main piston reaches it; and it arrives at the base of the cylinder at the same time as the main piston reaches the end of the return stroke. The gas and air which have previously been drawn in therefore find their way to the front of the inner piston through the space intervening between this piston and the cylinder.

GAS MOTOR ENGINES.—Dougill, J., of Manchester. No. 10,360; July 25, 1887. [8d.]

The first part of these improvements consists of an alteration in the movement of the piston and slides of the gas-engines described in patent No. 12,318 of 1884; the piston being made to travel as near as possible to the cylinder cover, for the purpose of thoroughly clearing from the cylinder all the products after combustion. The smaller slide which controls the supply of gas and air to the cylinder, is timed to admit air, but no gas until the piston has travelled one-tenth of its out-stroke; and the larger slide is timed to cut off the supply, and ignite the mixture, when the piston has travelled five-twelfths of its out-stroke. In this way a space equal to one-fifth of the pistons' travel remains between the piston and the cylinder end when the piston is at the end of its in-stroke—in other words, there remains a quantity of products after combustion equal to one-fifth of the piston displacement, within the cylinder after each exhausting stroke of the piston. The smaller slide is timed to admit gas immediately the piston commences its out-stroke; the larger slide, to cut off and ignite the mixture when the piston has travelled about one-third of its out-stroke. The second and third parts of the invention are entirely new manufactures, forming no part whatever of the patent referred to above—the second part consisting in the formation and arrangement of the parts which constitute a governor applicable to all forms of gas-engines; while the third part consists in the formation and arrangement of the parts constituting the slide-valve.

GAS MOTOR ENGINES.—Griffin, S., of Bath. No. 10,460; July 27, 1887. [11d.]

This invention relates to "twin" or double-cylinder engines in which each cylinder alternately gives an impulse to the crank-shaft when working at full power for the purpose of obtaining increased power with more frequent impulses, and consequently greater steadiness in running.

Hitherto, says the patentee, such engines have usually been made with each cylinder working with the double or "Otto" cycle—viz., one impulse (alternately in each cylinder) at every two revolutions of the crank-shaft when working at full power. The great disadvantage of this arrangement is that both pistons, when the cylinders are side by side, must necessarily make their outstroke at the same time; otherwise equal periods between the alternate impulses of each cylinder cannot be obtained. Such engines are thus thrown considerably out of balance (in consequence of the motion of both pistons and connecting rods being simultaneously in one direction), which for high speeds is objectionable.

In order to remedy these defects, the engine constructed according to this invention is made with two single-acting cylinders arranged side by side (either horizontally or vertically), and actuating the same crank-shaft; the cycle in each cylinder being that described in patent No. 4080, of 1883—i.e., an impulse takes place at the back end of each cylinder alternately every third revolution; consequently an impulse is communicated to the crank-shaft at every one-and-a-half revolutions, with equal periods between each impulse when at full power. This arrangement admits of the cranks being set opposite each other at such an angle that, while the piston in one cylinder is making an out-stroke, the piston in the other cylinder is making an instroke; perfect equilibrium being thus obtained.

In order to obtain still greater power, combined with great steadiness in running, two double-acting cylinders are placed side by side arranged to actuate the same crank-shaft—thus forming a double horizontal engine. The cranks are set at such an angle with each other, that the periods between each impulse will be equal when working at full power.

Another form of engine is obtained by fixing two such double-acting cylinders on a framing with their piston rods at right angles to each other (similar to an ordinary diagonal steam-engine); both cylinders actuating the same crank, with equal periods between the impulses when the engine is running at full power.

Fig. 1 shows a front elevation of the engine arranged with two single-acting cylinders.

The cylinders A are arranged parallel with each other in the water-casing T; the piston in each cylinder being connected by means of rods B, with the cranks C set opposite each other, and connected together by a central shaft, to the ends of which fly-wheels D are attached. The

operation of admitting the combustible charge alternately into each cylinder, as well as igniting it at the proper time, is performed by the slide-valve E, which is formed with a double [set of ports or passages (one set for each cylinder) similar to those described in the 1883 patent. The slide-valve receives its motion through the rod F from the crank G, which is attached to a spindle passing through the framing underneath the worm-box U, and having fitted at its opposite end the governor driving-wheel M. Motion, in the proportion of one revolution to three of the crank-shaft, is imparted to this spindle by means of a worm on the crank-shaft working in the worm-box U, which gears with a worm-wheel attached to the spindle (not shown in the drawings). The exhaust-valves K (only one of which is indicated) receive motion from the cam H, through the levers I and rods J. The admission of gas is regulated by the gas cam N, which opens the gas-valve at the proper time, by means of the rod O; this rod being moved either into or out of contact with the gas-valve by the action of the governor L, through the medium of the lever P and rods Q and R. The interior of the cylinders, as well as the slide-valve, is oiled by means of the lubricators S.

The operation of the engine is as follows:—The entire cycle being completed in each cylinder in three revolutions of the crank-shaft, as described in the patent already referred to, an impulse will take place in the right-hand cylinder, causing the crank-shaft to make one entire revolution and a half, at which point the crank C will be on the bottom centre and the combustible charge in the left-hand cylinder fully compressed. The slide-valve E having now completed its stroke in the opposite direction, the charge in the last-named cylinder is ignited, imparting an impulse to the crank C causing the crank-shaft to revolve a further one and a half revolutions. At this point the right crank is again in the position shown in the drawing; and at the same time the entire cycle in the right cylinder having been completed, an impulse is again about to take place, which will be followed on the completion of a further one and a half revolutions of the crank-shaft by an impulse in the left cylinder. When the engine exceeds its normal speed, the governor B will rise; and thus, by means of the rods Q and R and the lever P, move the rod O out of contact with the gas-valve, and shut off the supply of gas. The operations of charging, igniting, and exhausting are not described; being similar to those in the 1883 patent.

LIGHTING AND HEATING BY GAS.—Guibout, O. E., of Dieppe, France. No. 10,558; July 29, 1887. [8d.]

A vertical section of this apparatus is shown in the engraving. It consists of a central gas-tube A, on the upper part of which is screwed a cast-iron cylindrical box B, provided with four channels through which the gas issues. A rod C is screwed on the top of the box; and a tube D, of enamelled copper, is arranged below the box B and concentrically to the

tube A. A ring or collar E of fire-clay rests on the top of the tube D. A collar F, provided with arms and kept in position by a pressure screw, is adapted to the lower part of the gas-tube for the purpose of supporting the glass globe G; while a cast-iron box H, resting on the top of the box B, surrounds the latter. The boxes are adjusted on each other in such a manner that the gas issuing through the end openings of the channels fills the space between the two boxes, and issues at the lower part in the form of an annular sheet. The box H is besides secured in its place by a stirrup I, held in a fixed position on the top of the box by means of a nut screwed on the rod C. A perforated cylinder K, of enamelled copper, surrounds the box H and supports

at its lower part a crown of fire-clay L, which in its turn supports a fire-clay dome M, kept in position by a nut also screwed on to the rod C. Lastly, a triangular support N receives a cover O and the chimney P. This cover is of enamelled copper, and composed of a conical part O and of a circumferential compartment Q, provided with annular openings, and with a row of small holes.

Gas enters through the tube A, and descends through the space between the boxes B and H, and, coming out in an annular sheet, burns between two currents of air—namely, one coming from the tube D, surrounding the central gas-tube A, and issuing between the refractory collar E and the box B; the other formed of air which has risen into the refractory dome M, and then descended between the inner surface of this dome and the perforated cylinder K. The current passes through the cylinder, and comes out above the flame between the box H and the refractory crown L; and the two currents become heated by their contact with the heated parts of the flame. The gases of combustion escape round the dome M; while the air on entering passes through the holes provided for the purpose, and issues so as to keep the glass globe cool.

IGNITING APPARATUS FOR GAS-ENGINES.—Abel, C. D.; communicated from the Gas Motoren Fabrik Deutz, Deutz, Germany. No. 11,444; Aug. 22, 1887. [8d.]

This invention relates to apparatus for igniting the charges of gas engines by means of a portion of the charge brought in contact with the interior of a tube, arranged centrally within an annular Bunsen burner, the flame of which effectually heats it so as to make the ignition of the charge within it perfectly reliable. At the same time, the flame is rendered of a reducing character and consequently protects the tube from injury through oxidation.

In operating the apparatus, a portion of the compressed combustible charge in the cylinder passes back through the igniting channel into the horizontal channel of the burner, and also partly up into the heated igniting-tube. The flame travels down the tube, and thence in both directions in the horizontal passage, and finding no escape at the outer end of it, is projected by the expansion due to the combustion through the igniting passage into the cylinder, where it effects the ignition of the charge. The tubular extension of the burner passage, besides assisting in the projection of the flame, also serves, on the removal of its cap, for the withdrawal of any solid deposits that may be carried backwards into the burner from the cylinder by the entering compressed gaseous mixture.

Correspondence.

[We are not responsible for the opinions expressed by Correspondents.]

THE PHOTOMETER QUESTION AT THE GAS INSTITUTE MEETING.

SIR,—Having undertaken to make myself as useful as possible to our friends and my colleagues of the Société Technique during their visit, I was unavoidably absent, "personally conducting" a party, at the time when Mr. Dibdin's paper was read at the recent meeting of The Gas Institute.

If I had read rightly the augury from the appearance of the skies, I might have inferred that the poor old Evans photometer, together with others, were in stormy weather, with variable currents, in Great George Street. But though I had been favoured with a sight of Mr. Dibdin's paper, I did not anticipate that the results of his experiments, or the enthusiasm of the author, would have so completely carried away The Gas Institute as it appears to have done. I congratulate Mr. Dibdin on the success of his communication. I am told that the "open photometer" (?) was generally approved of, and that the Evans photometer was relegated to the dust-bin, or to some other proper place where such exceedingly badly-conducted instruments (they are said, I am told, to cause a very respectable class of men to commit "a nightly fraud") ought to go.

I do not deny that I am surprised at the deft manner in which the photometer question was, as I was informed, settled. I have devoted many years of my life to the subject of photometers and photometry; and although I do not now consider it to be a difficult thing to make a scientifically accurate photometer, I think it is a very difficult thing—considering the important and complicated questions involved in the verification of the illuminating power of the gas supplied to the public, under existing Acts of Parliament—to settle a form of photometer satisfactory to all parties, particularly for London. But "*Audi alteram partem*" is a motto not often lost sight of by scientific men; and I ask leave to freely translate it thus: Hear the maker of the Evans photometer before you condemn it. The discussion of Mr. Dibdin's paper at The Gas Institute meeting is past and gone, and I cannot now conveniently join in it; but I will ask your permission to put before your readers some remarks on photometers and photometry, including the Evans photometer, after I have read your report of the discussion which took place at the Institute meeting.

I intended to have read at the recent meeting a paper on "Standards of Light." But, from some cause or other, my name did not appear on the list; and I may say that I am not sorry for it, considering the great importance of the subject, and the limited time the Institute had at its disposal for scientific work. I think that the subject of photometers, "open" and "closed" is of such a nature that the columns of the JOURNAL are much better adapted for its thorough consideration than The Gas Institute meeting. Mr. Dibdin has made a valuable contribution to the literature of the question, although I hope to be able to show your readers that his experiments will bear another interpretation of the conclusions he draws from them than that which he gives to them.

33, Bold Street, Liverpool, June 23, 1888.

WILLIAM SUGG.

MR. CARPENTER'S PAPER ON THE PRINCIPLES OF GASEOUS FIRING.

SIR,—I am sorry not to have been present at the meeting to hear Mr. Carpenter's paper, although I have to confess to a feeling of disappointment on reading it in your last week's issue. It betrays on the part of the author a superficial acquaintance with his subject, for which I was scarcely prepared; and this is coupled with a sort of happy ignorance of much that has been achieved outside his own immediate sphere.

It is surely idle to advance the fact that air takes up heat rapidly, for the purpose of proving that it becomes heated in its passage through a single narrow flue, when his own experience proves the inferiority of this treatment—regarded simply as a means of heating air—as compared with that which is secured in a regenerative furnace. It must be equally idle to deny the possibility of restoring an appreciable amount of waste heat to the furnace, when we have the testimony of one of his own supporters, Mr. Valon, to the contrary. Nor does it appear any more reasonable on his part to raise, for the purpose of vindicating his position, the old and well-worn bugbears of cost and failure, or to attract the imagination of his audience by highly-drawn references to "cunningly devised titles, &c." Our faith in a thin conducting medium is by no means so extinct as Mr. Carpenter would have it to be supposed; nor, as to comparative cost, is he entitled to indulge in unlimited self-congratulation; while failure, from which he has, it is true, not ingloriously secured himself, has, to others, largely proved but the prelude to signal success.

Without, however, pursuing the many errors with which it abounds, the paper fairly suggests a reflection upon the present position of the subject of it. It is now about ten years since it became pretty generally known in this country that all, and more than all, the advantages claimed by Mr. Carpenter for his system of simple firing were being obtained in many places abroad by one or other of the various adaptations of the regenerative system. Fully five years ago, these advantages had begun to be secured amongst ourselves; and at the present time it is no uncommon thing to hear in the provinces of a production per mouthpiece of 8000 or 9000, or 10,000 feet and upwards. What part has London taken in this great advancement? What has she, with her picked intelligence and resources practically unlimited, contributed to this result? Absolutely nothing; and Mr. Carpenter's paper indicating—as may be reasonably supposed—the extreme height to which our Metropolitan brethren have managed to rise after ten years of effort, may indeed be said to "point a moral," if not to "adorn a tale."

Birmingham, June 30, 1888.

CHAS. HUNT.

MECHANICAL V. HAND STOKING AT THE MANCHESTER CORPORATION GAS-WORKS.

SIR,—Referring to the letter and figures of Alderman King respecting the cost of carbonizing by my machinery, I wish to say that, in writing to Mr. May, I endeavoured to state every point of the cost I asked for so fully in detail that no one could mistake what was included in it. But Mr. King has evidently fallen into the common error of supposing the

words "cost of carbonizing" to mean that in every place the same items are charged to the carbonizing account. That is a supposition quite at variance with fact, and should be carefully avoided.

If Mr. King will kindly read the letter which I wrote to Mr. May, he will find that I ask for the cost including "wages for coal wheeling, breaking, elevating, conveying it into the hoppers, stokers, firemen, coke wheelers—in fact, all charges from the taking of coal from the coal stores to the tipping of the coke in the yard." My principal object in so carefully defining the work included in my figures, was to enable engineers who might honour me by reading the letter, to compare for themselves the cost of doing their work under the existing conditions, with the cost by machinery.

When these expenses are taken for the Rochdale Road works of the Manchester Corporation, my figures will be found to be correct; and no mistake whatever has been made by me. The number of men employed, and the wages paid to them for doing the work at Manchester, are as follows:—

No. 1 House (with "Manual" Machinery).

The amount of coal carbonized per day of 24 hours is 183 tons 15 cwt.

	Per Day.	s. d.	£ s. d.
48 men to draw and charge the retorts, open and close the lids, auger pipes, wheel coke into the yard, and attend to the furnaces	5 0	=	12 0 0
10 coal wheelers and coke quenchers	4 2	=	2 1 8
2 engine-drivers	5 0	=	0 10 0
			£14 11 8

Which works out 1s. 7d. per ton of coal carbonized.

No. 2 House (with "Compressed Air" Machinery).

The amount of coal carbonized per day of 24 hours is 192 tons 10 cwt.

	Per Day.	s. d.	£ s. d.
12 men to draw and charge the retorts and close lids	5 6	=	3 6 0
8 men to open lids, auger pipes, and wheel away coke	5 0	=	2 0 0
16 firemen	5 0	=	4 0 0
10 coal wheelers and coke quenchers	4 2	=	2 1 8
2 engine-drivers	5 0	=	0 10 0
			£11 17 8

Which works out 1s. 2-82d. per ton carbonized.

For the same work done by hand at Manchester, Mr. King will know that the Corporation pay 2s. 6d. per ton.

The cost of superintendence, retort setters, and men repairing retorts, included in the carbonizing account at Manchester, would require to be added to the cost per ton given above; but this item would be exactly the same either for machine work or hand stoking, and does not affect the comparison.

As regards the figure given by Mr. King for repairs to machinery, I should like to point out that the machinery in No. 1 house received its first thorough overhaul during the nine months selected by Mr. King. It had then been at work for three seasons, and had dealt with about 163,000 tons of coal during that period. Before being stopped for repairs it had been working that season for 240 days continuously. The machinery in No. 2 house had been running, night and day without intermission, for 546 days, up to July, 1883, during which period about 104,500 tons of coals were carbonized. It was then thoroughly overhauled and repaired during the nine months in question.

As the portion of the wear and tear account due to the general overhaul was caused by wear which had taken place during the whole time the machinery had been in operation, surely Mr. King should have calculated that large proportion of his cost upon the larger weight of 163,000 tons in one case and 104,500 tons in the other.

In order to make a correct comparison between hand and machine stoking, the wear and tear of rakes, scoops, and shovels should be added to the figure for hand stoking. This is a detail of considerable amount; but, as it is inevitable, it has generally been overlooked in such comparison.

JOHN WEST.

Manchester, June 30, 1888. Late Chief Engineer to the Manchester Corporation Gas Department.

THE SEALING OF REGISTERS OF SHAREHOLDERS.

SIR,—In reply to the question which "Limited Company" addresses to me in your last issue, will you permit me to say that the terms of your original correspondent's inquiry obviously refer to incorporated companies which are subject to the provisions of the Companies' Clauses Acts, and not to companies registered under the Limited Liability Acts. The latter contain no provisions as to sealing the register, but section 9 of the Companies' Clauses Consolidation Act, 1845, enacts that "the Company shall keep a book, to be called the 'Register of Shareholders;'" . . . and such book shall be authenticated by the common seal of the company being affixed thereto; and such authentication shall take place at the first ordinary meeting, or at the next subsequent meeting of the company."

Points of company law and practice possess an interest for me; and I shall be pleased to hear from "Limited Company" and your original correspondent if they care to go further into the matter.

Commercial Gas-Works, Stepney, E., June 17, 1888.

H. D. ELLIS.

MR. N. H. HUMPHRYS ON PURIFICATION BY OXIDE OF IRON.

SIR,—I have read somewhere of an old lady whose feelings were, on occasions, apt to be "too much for her;" and Mr. John T. Sheard, in his letter published in the last number of the JOURNAL, shows strong indications of similar tendencies. Possibly it is the turmoil of conflicting emotions that has obfuscated his reasoning powers. Firstly, we have him struggling with "considerable reluctance;" but this is speedily overcome by the prospect of some reader, taking "his first lessons on the scientific aspects of an important branch of modern (I) gas manufacture," being misled whilst undergoing that operation, and turning an accusing eye on him (Mr. J. T. Sheard) for his "injustice and ungenerosity" in refraining from setting forth the truth. Then a little further on he tells

us that the reason of his writing is the fear that my article, if uncorrected (!), must tend to "aggravate the former confusion." How the use of such unmeaning terms is to assist towards perspicuity is a mystery to me. After this, he is troubled with a fear lest certain "ignorant" readers should interpret one of the columns in a table as meaning something entirely different from the full explanation of it given in the article—an explanation quite as full and complete as that which he has thought necessary to add. If any reader is so foolish as to pick out one portion from this or any other article, and put his own construction upon it, without regard to the context, he is certainly likely to go wrong, even with the advantage of Mr. Sheard to correct and explain. All this sort of thing is simply a transparent device intended to conceal his real object in writing, whatever it may be.

Having "briefly" stated his principal objection in a sentence of about eighty words, Mr. Sheard proceeds to make uncalled-for assumption as to my ignorance, or otherwise, respecting a certain contribution to the Chemical Society, and also of a communication to the JOURNAL. The said contribution and communication, in his opinion, settle the whole question of the "scientific aspects," &c.

Taking the contribution first, I have simply to remark that it cannot be taken as *directly proving* anything about the behaviour of ordinary "oxide" in coal gas purifiers. The material used by Mr. Lewis T. Wright was not ordinary commercial oxide, but a compound prepared by precipitating a solution of a ferric salt, carefully washing the precipitate, drying at 212°, and keeping in a desiccator till required. This compound was proved to have a composition represented by the formula $\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$. Some experiments were tried by passing dry sulphuretted hydrogen, containing 15 to 20 per cent. of free hydrogen, through it, until saturation. The results obtained under these conditions appear so remarkably conclusive to the mind of Mr. Sheard, as to render it imperative not to allow even the mention of any theory that does not wholly agree with them. I wish it to be observed that, in my article, the existing theories were simply stated; no opinion was expressed upon them, and no attempt was made in the way of controverting the three principles so dogmatically laid down by my critic. I certainly wrote down the formula $\text{Fe}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$; and the alteration of this to $\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$ appears to be the only genuine correction he wishes to make. Looking at the facts that Mr. Wright had to take careful precautions in order to obtain the compound $\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$; that some of his samples contained a considerable excess of water beyond that allowable by that formula; that he refers to the substance above mentioned whilst in the moist state (a condition similar to that in which it would probably exist in ordinary purifiers, as an excess of water is always present) as $\text{Fe}_2\text{H}_2\text{O}_6$ or as $\text{Fe}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$ —it appears to me that the endeavour to drag in this paper in support of the idea that the proper formula for the active principle in "oxide" as it exists in the purifier is $\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$ is simply a perversion of fact. I quite agree that Mr. Wright's experiments are conclusive and incontrovertible, so far as the particular compound used is concerned; but I cannot also consent to the assertion that they prove, in an equally certain manner, the reactions that take place with an impure ferric hydrate in the presence of an excess of water, treated with a gas containing perhaps less than 1 per cent. of sulphuretted hydrogen.

Now we come to Mr. Sheard's communication. His method of procedure is so different from that obtaining in ordinary practice, that, whilst cheerfully admitting that it throws valuable light on the subject, I cannot accept it as so conclusive as to prove every other theory to be utterly absurd and unworthy even of mention. My reason for giving prominence to Professor Wanklyn's views is the fact that they are based, if I am rightly informed, on actual study and experiment in the purifier-house itself; and as such I consider them preferable to those based on laboratory experiments, coupled with conditions of an artificial character to a greater or less extent. They certainly deserve more respect than Mr. Sheard extends to them.

In concluding, I may remark that the appearance of Mr. Sheard's letter in the same issue of the JOURNAL which contains the editorial remarks under the head of "The First Two Gas Institute Papers" is a strange coincidence. He fully illustrates the manner in which the defects to which speakers in *viva voce* discussions are liable may also extend to written discussions. The speaker on a paper which he has only just heard, perhaps more or less imperfectly, certainly has some claim to indulgence if he strays from the reader's meaning; but similar consideration can scarcely be extended to one who, having had the opportunity to read a paper carefully and at leisure, misrepresents the same, and confuses the points at issue by bringing in extraneous matter.

Salisbury, June 30, 1888.

N. H. HUMPHRIES.

AN IMPROVEMENT IN LIGHTING.

SIR,—Although regenerative gas-burners are useful for a certain class of lighting, it may safely be said that they are by no means suited for all-round domestic use, owing to their cost, their absolute failure if a glass is broken, and the attention required to keep the glasses clean, with the consequent extra liability to breakage from the necessary handling. I have for many years advocated the use, for workshop purposes, of ordinary flat flames placed horizontally, in which position they give no shadow downwards, and with an ungoverned service the light is undoubtedly increased as compared with a vertical flame. But this system is not suited for ordinary sitting rooms, partly on account of its appearance, and also because the flame cannot be turned partially down without causing flickering and smoke.

I have recently adopted an arrangement which, whilst increasing the downward light by about 40 per cent., causes no unpleasant upward shadow, and is free from all objections for ordinary domestic service. It is simply an ordinary flat-flame burner with one of the recent patterns of opal globe with a wide opening about six inches diameter at the bottom. The new departure consists of the use of a special gallery or holder which raises the bottom of the globe at least an inch above the top of the burner—converting the globe into a reflector. The toning down of the top light is hardly appreciable, whilst the opal globe throws a strong and shadowless light downwards exactly where it is required. For practical lighting one No. 4 burner with this arrangement will do at least as much as three with ordinary close opal moons, and as much as two with partially ground clear-glass globes. The light will, in fact, compare favourably with many, probably with

most of the regenerator burners in use; and it has the advantage of being cheap, simple, unpatentable, and satisfactory from a decorative point of view.

I have forwarded one of the arrangements, exactly as we use them in my own house, and as made for many friends. They are well adapted for replacing sun-burners for top lights in shops and windows, giving a warm shadowless light which is exceedingly pleasant. We shall shortly have these lights fixed in our London show-rooms; and as they are both cheap and easy to copy, no doubt they will soon come into extended use.

Warrington, June 29, 1888.

THOS. FLETCHER.

Parliamentary Intelligence.

HOUSE OF LORDS.

MONDAY, JUNE 25.

The Hexham Local Board Bill was reported from the Select Committee with amendments.

TUESDAY, JUNE 26.

The Frodsham Gas and Water Bill was reported, with amendments.

The Llanelly Local Board Bill was brought from the Commons, read the first time, and referred to the Examiners.

The Gas Provisional Orders (No. 1) Bill was brought from the Commons, read for the first time, and referred to the Examiners.

The Nelson Local Board Bill was referred to a Select Committee, consisting of Lord Basing (Chairman), Viscount Torrington, Lord Brougham and Vaux, Lord Hamilton of Dalzell, and Lord St. Levan; to meet on Thursday, July 5.

THURSDAY, JUNE 28.

The following Bills received the Royal Assent by Commission:—Barnstaple Water Bill, Electric Lighting Act, 1882, Amendment Bill, Folkestone Water Bill, Glasgow Corporation Bill, Halifax Corporation Water Bill, Hamilton Water Bill, Helston and Porthleven Water Bill, Keswick Gas Bill, Riddings District Gas Bill.

The Examiners reported that the Standing Order applicable to the Gas Provisional Orders (No. 1) Bill has been complied with.

The Limsfield and Oxted Water Bill was reported, with amendments.

The Water Provisional Orders (No. 2) Bill and the Gas and Water Provisional Orders Bill were read a second time, and referred to a Committee of the Whole House.

FRIDAY, JUNE 29.

The Examiners reported that the further Standing Orders applicable to the Llanelly Local Board Bill have been complied with.

The Frodsham Gas and Water Bill was read the third time, with the amendments, passed, and sent to the Commons.

The Gas Provisional Orders (No. 1) Bill was read a second time.

ELECTRIC LIGHTING ACT 1882 (PROCEEDINGS).

A report by the Board of Trade respecting the applications to, and proceedings of the Board under the Electric Lighting Act, 1882, during the year 1887 was presented.

HOUSE OF COMMONS.

MONDAY, JUNE 25.

The Hamilton Water Bill (Lords) was read the third time and passed, without amendment.

The Llanelly Local Board Bill, as amended, was considered, read the third time, and passed.

The Lincoln Corporation Bill (Lords) was read a second time, and committed.

TUESDAY, JUNE 26.

The Henley-on-Thames Gas Bill (Lords) and the Hinckley Local Board Water Bill (Lords) were read the third time and passed, with amendments.

The Gas Provisional Orders (No. 1) Bill was read the third time, and passed.

The Edinburgh and Leith Corporations' Gas Bill (Lords) was referred to a Select Committee, consisting of Mr. Abel Smith (Chairman), Mr. W. L. Bright, Mr. Seager Hunt, and Mr. McCartan; to meet on Thursday, July 5.

WEDNESDAY, JUNE 27.

The *locus standi* of gas consumers, ratepayers, and owners of property in Edinburgh and Leith, petitioners against the Edinburgh and Leith Corporations' Gas Bill (Lords), has been disallowed.

THURSDAY, JUNE 28.

The South Lincolnshire Fen Water Bill (Lords) was read the third time and passed, with amendments.

THE NORTHERN COAL TRADE.—There has been increased activity in the steam-coal trade of the North during the past week. The shipments have risen considerably, and the local requirements have also been greater; so that the collieries have been generally fully employed. Price are said to be "stiffer;" but there have been no higher rates generally paid. For best steam coal the price has been about 7s. 6d. per ton net, though old contracts are running even lower. Second-class coal varies from 7s. down to 6s. 6d. per ton; but the small steam coal is weaker. For gas coal the demand is very low, except in one or two instances; and it is said that as low as 5s. 6d. has been accepted for good gas coal. The great contracts for The Gaslight and Coke Company are believed to have been renewed on terms which do not show much change from those they will replace. House coal is extremely dull just now. Coke is steady; and good gas coke is in demand.

OPENING OF WATER-WORKS AT HOWDEN.—On the 25th ult. the water-works at Howden were formally opened by Mrs. Clark, of Knedlington Hall, the wife of the Chairman of the Howland Water Company. The water has been obtained from a deep boring on land purchased of Mr. T. S. Clark. Mr. Clark said the Company had been actuated with the desire to give the people of Howden a supply of pure water, from the want of which they had suffered greatly. Mr. Fairbank, C.E., the Engineer, having explained the details of the scheme, and invited the people of Howden to inspect the works at Asselby, the Rev. W. Hutchinson (Vicar of Howden) referred to the fact that some of the sickness in Howden which had been ascribed to the interposition of Providence was really due to bad water. He congratulated them heartily on the completion of the works that day. Amid cheers Mrs. Clark then turned on the water, and declared the Howden Water-Works duly and formally opened.

HIGH COURT OF JUSTICE—QUEEN'S BENCH DIVISION.

SATURDAY, JUNE 23.

(Before Justices CAVE and WILLS.)

SLATER v. MAYOR AND CORPORATION OF BURNLEY.

This was an appeal from the County Court of Lancashire, held at Burnley, and was a test case, raising a question as to the basis of water-rental for the borough for the quarter ending Dec. 25, 1887, and also as to the general point whether an overpayment of water-rent can be considered a compulsory payment, and therefore not recoverable, simply because the corporation supplying the water have power to cut it off in case of default in payment.

Mr. HENN COLLINS, Q.C., and Mr. SUTTON appeared for the Corporation of Burnley; Mr. PHILBRICK, Q.C., and Mr. D. WARD for the respondent (Mr. Slater).

The proceedings in the first instance were reported in the JOURNAL for May 22 last (p. 922); and the facts were not disputed. The Corporation, who under their Local Acts supply water to the borough, charged £8 15s. 4d. for the water-rent on several houses; such amount being 5 per cent. on the gross rental. The sum if based on the rateable value (which Mr. Slater contended for) would have been £7 3s. 10d., the provisions of the Local Act allowing a charge of 5 per cent. on the annual value. The plaintiff paid on the full amount asked, and then brought an action to recover the difference (£1 11s. 6d.), as being paid under duress. The Corporation have power to cut off the water if the water-rent due is not paid; the County Court Judge held therefore that the payment was not voluntary, and might accordingly be recovered. Judgment was entered for the plaintiff for the amount claimed. It appeared that the Corporation had based the next water-rate on the net rateable, and not on the gross annual value; and the case was therefore important in relation to the right of all the other ratepayers who had paid the rate in question to recover the excess. It was now argued for the Corporation that, as there had been no threat to cut off the water, whatever their powers might be, there had been no compulsion, and the payment by the plaintiff was voluntary and could not be recovered by him. There was also a question, on the construction of the Local Acts, 34 & 35 Vict., cap. 154, and 46 & 47 Vict., cap. 77, as to whether the Water-Works Clauses Act, 1847, was incorporated. The appellants argued that it was; and contended that this was a dispute as to annual value under section 68 of that Act, and ought therefore to have gone before two Justices, and not the County Court Judge.

Judgment was delivered to-day.

Justice CAVE held that the payment was a voluntary one, and therefore was not recoverable; consequently there must be judgment for the Corporation. The ground on which the County Court Judge decided that the payment was not voluntary was simply that the Corporation had the power to cut off the water. There had not even been a threat of so doing, or of any legal proceedings. This was not a sufficient ground; and as it was the only ground, the judgment must be reversed. As to the next point, though not now necessary for the decision of the case, for the benefit of the County Court Judge, he (the learned Judge) would deal with it. On the construction of the Acts, it was clear that the Water-Works Clauses Act, 1847, was not incorporated either by the Burnley Improvement Acts of 1871 or 1883; and therefore the County Court Judge was right in this respect, under the circumstances. There would be judgment for the defendants, but without costs.

Justice WILLS concurred in holding the payment voluntary. As to the second point, the Local Act of 1883, by section 5, provided that that Act should be carried into execution by the Corporation according to the Municipal Corporations Act, 1882, the Public Health Act, 1875, the Local Act of 1871, and "other Acts respectively for the time being in force and affecting the Corporation as a municipal corporation and sanitary authority;" and by section 6 it enacted that certain Acts, so far as they were "applicable and not inconsistent with that part of the Act," should be incorporated. The Water-Works Clauses Act was one of these. This was a specimen of a very slovenly system of drafting Acts of Parliament, which was most unsatisfactory, and a source of perpetual uncertainty. In such a case it was necessary to go backwards and forwards from Private Acts to the Public Acts, and then back again to the Private Acts, and so on. It was enough to say here that section 68 of the Water-Works Clauses Act, 1847, was not applicable to that part of the Local Act of 1883, and was, therefore, not incorporated.

FRIDAY, JUNE 29.

(Before Justice CAVE.)

SOUTHWARK AND VAUXHALL WATER COMPANY v. DICKENSON.

This was an action to recover the sum of £46 14s. for water supplied to premises of which the defendant is the owner.

Mr. M'CALL, who appeared for the plaintiffs, said that on May 30, 1883, the defendant entered into a contract with the Company by which he agreed to pay at the rate of 1s. per 1000 gallons for a "domestic" supply of water; and if this agreement was binding, the action was really undefended. The defendant owned a large block of buildings, and he was anxious to have them supplied by one communication-pipe and cistern; and, with a view of saving £700 or £800, the cost of the fittings for a domestic supply, he made a contract with the Company, specifying in substance, that if they would supply him with water for domestic purposes in a way in which he could not compel them to supply him, he would pay 1s. per 1000 gallons for it. The water was supplied, and now, when asked for payment, the defendant raised the contention that by the Company's Act of Parliament the Company were prohibited from charging more than 6d. per 1000 gallons. The Act really said nothing of the kind.

Mr. MIRAMS contended that the contract was *ultra vires*, and could not be enforced. If the defendant paid according to the rateable value of the premises, the charge would only amount to £26 4s. 6d.; and therefore the Company had for some time been overcharging. The arrangement between the parties was really for the benefit of the Company, as they had one responsible person, instead of 230 poor tenants, to look to for the water-rate. They might, if they thought fit, put an end to the agreement, and supply on the rateable value. Having made a charge beyond the rate allowed by the statute, the Company could not recover it. The defendant, by way of counter-claim, asked for repayment of £104, being the amount of the alleged overcharge.

Justice CAVE: I am of opinion that judgment must be entered for the plaintiffs. The relations between the Company and the public are to be found in sections 53 and 57 of the Act. By section 53, an owner can compel the Company to supply water for domestic purposes at a certain rate, which depends upon the value of the house. By section 57, the Company may insist on the owner having his water by meter; and the owner, if he wants water for other than domestic purposes, may insist upon the Company supplying it, but in that case he can only insist on their supplying it by meter. Now, neither of these proceedings has been adopted in this

case. The owner has not required a supply on the footing of section 53; and the Company did not, at their own instance, require him to have water by meter. The purposes for which the water was supplied were ordinary domestic purposes; and, consequently, the owner could not come under section 57. This particular case, therefore, is one which was not provided for by the Act of Parliament. The Act proceeds to say that the parties shall make agreements on their own terms, if it suits them to depart from those provisions which have been enacted for their mutual protection. If it suits the owner better to have his water for domestic purposes by meter, he cannot compel the Company to supply it to him by meter; but if he says, "I know I cannot make you give it by meter, but I will pay you so much per 1000 gallons if you give me a supply by meter," I see nothing in the Act which could make such a contract *ultra vires*. The express purpose for which the Company is formed is that of supplying water to the public. There are things which, no doubt, limit the charge that can be made if the person requiring a supply of water chooses to adopt the provisions in his favor that are to be found in the Act. If, for instance, he gives the necessary notice provided by section 53, he can have the water at the prices mentioned in that section. If it does not suit him to do this, and he asks to have the supply in some other way which suits him better, I see nothing in the Act of Parliament which says it is *ultra vires*. He does not want the protection—he prefers not to have the protection provided for him by section 53; and this being so, I do not see why, on ordinary principles, he should not be allowed to make his own terms as to the amount he will pay for the water. Section 57 does not apply to the case, for he cannot demand a supply for ordinary domestic purposes under that section. I think there is no defence to the action; and consequently there must be judgment for the plaintiffs on the claim and counterclaim for £46 14s., with costs.

On the application of defendant, his Lordship granted a stay of execution, with a view to an appeal, upon the sum of £70 (in addition to the £46) being brought into Court.

SOUTHWARK POLICE COURT.—MONDAY, JUNE 25.

(Before Mr. SLADE.)

CHARGE OF STEALING WATER.

To-day Arthur Linsey was summoned for stealing a quantity of water belonging to the Southwark and Vauxhall Water Company. The defendant is the occupier of No. 443, Old Kent Road; and in 1886, the defendant not paying the water-rate, the supply was cut off. Although the defendant and his family remained in possession, he did not apply for a fresh supply of water. After a time, this aroused the suspicion of the officers of the Company; and the back premises were visited by an inspector, who, thinking that probably the defendant obtained his water from the supply to No. 441, removed the pipe some distance away. Subsequently a detective, acting on instructions, placed himself in the garden, and late at night on the 7th of June he saw a portion of the fence removed from the defendant's place, and a hand put out which affixed some tubing to the supply. In this way the defendant's water-butt was filled. When this was done, the hand was again put out to get the tube away; and on this the officer seized the hand, which, after a struggle, was found to be the defendant's. The defendant was told that he would be charged with stealing the water; and he said, "I'm done."

Mr. WILKINS, who prosecuted, said the Company knew that this kind of larceny was more frequent than could be supposed, but there was very great difficulty in proving the offence, and the prosecution therefore desired that some term of imprisonment should be inflicted on the defendant, if the case were settled at that Court.

Defendant declined to submit to the Magistrate's jurisdiction; and he was committed to take his trial at the next Surrey Sessions.

DAMAGED SEWERS AT BIRKENHEAD.—A Local Government Board inquiry has lately been held by Mr. S. H. Terry at Birkenhead, with reference to the application of the Corporation of that town for sanction to borrow £6000 for the repair of sewers and gas and water pipes damaged by the Mersey Railway Company. The Company was represented by Mr. Tobin, who contended that the work could be done for very much less; the Company being ultimately responsible for the cost. The result of the inquiry has not transpired.

THE PUBLIC LIGHTING OF BECKENHAM.—As a result of the discussion at Beckenham in regard to the adoption of oil lighting, to which reference has been made in the previous issues of the JOURNAL, the Bromley Gas Company have made a reduction of 2s. per lamp per annum in connection with the lighting of the portion of Beckenham parish in the Bromley district; and though the price, notwithstanding the reduction, is still higher than that charged by the Crystal Palace Gas Company in another part of the parish, the Local Board have accepted the new arrangement.

PLYMOUTH GAS COMPANY.—The annual general meeting of this Company was held last Thursday, under the presidency of Mr. G. Henderson, the Chairman. The Directors in their report stated that after paying the authorized half-yearly dividend, in January last, the balance remaining to the credit of the profit and loss account amounted to £28,970 17s. 11d. At Michaelmas last, the price of gas to private consumers was reduced from 1s. 10d. to 1s. 9d. per 1000 cubic feet, and the public lamps from £2 12s. 7d. to £2 11s. 3d. per light per annum. The Directors recommended that, in accordance with the Act of 1879, a dividend of 12s. 3d. per share on the original shares, and 9s. 9d. per share on the additional shares, free of income-tax, should be declared for the half year ending March 31 last; being at the rate of 12½ per cent. on the original, and 9½ per cent. on the additional shares—the balance to be carried to the next account. The Chairman moved the adoption of the report, and the motion was carried; as were also the customary resolutions with respect to the dividends.

HAYWARDS HEATH WATER SUPPLY.—In a recent issue of the *Mid-Sussex Times* appeared the report of a speech made by Mr. G. W. Bailey at a dinner at Hurstpierpoint, in the course of which, referring to the water supply of the district, and to the delay by the Mid-Sussex Company in commencing work, he said that "if the so-called 'bogus company' [the Haywards Heath and District Water Company] had obtained their Provisional Order, it would have been started by that time." Mr. H. J. Robus, the Chairman of the Mid-Sussex Water Company, has written to the Editor on this matter. He points out that the requirements of the opposition Company were put down at £17,000; and yet one of their own witnesses at the inquiry proved this to be insufficient by £6000. He expressed the belief that had the inquiry lasted one more day, they would have acknowledged that their scheme would require £50,000 to complete, and then be the most extravagant and ill-advised scheme that could possibly have been introduced. He says the Directors of the Mid-Sussex Water Company are anxious to commence operations; and as soon as the Royal Assent is obtained for their Provisional Order, the work will be commenced forthwith, and pushed forward with all the vigour possible. He regrets the delay, and hopes that by this time next year the district will have an abundant supply of pure water.

Miscellaneous News.

GAS-LIQUOR WORKS AND THE ALKALI ACT.

In another part of the JOURNAL to-day, we give an epitome of the twenty-fourth annual report of the Chief Inspector under the Alkali, &c., Works Regulation Act, 1881 (Mr. A. E. Fletcher). As there stated, it embraces the proceedings during the past year of himself and his colleagues, the various District Inspectors—the reports of the latter gentlemen following his own. As gas-works come under inspection, so far as concerns the manufacture of sulphate of ammonia, the portions of the reports dealing with this matter are of interest to our readers, and we therefore reproduce them practically in their entirety. It should be stated that the entire area in England and Ireland under the supervision of the Chief Inspector is divided into seven districts, each having a Sub-Inspector, as follows:—(1) Ireland, Mr. W. S. Curphey, F.I.C., F.C.S.; (2) North of England, Mr. B. E. Smith, F.I.C., F.C.S.; (3) Cheshire, North Wales, and part of Lancashire, Mr. E. G. Ballard, with whom is associated Mr. J. Affleck, M.A., D.Sc., as an additional Sub-Inspector for the Widnes sub-district, comprising Widnes and Runcorn; (4) East Lancashire and Yorkshire, Mr. R. Forbes Carpenter, F.I.C.; (5) South Midland, Mr. E. Jackson, F.C.S.; (6) South-West of England and South Wales, Mr. A. C. Fryer, Ph.D., M.A.; (7) South-East of England, Mr. Brereton Todd. Scotland—which is divided between Dr. Blatherwick and Mr. W. S. Curphey—is the subject of a separate report. The reports of all these gentlemen are, of course, addressed to the Chief Inspector.

In No. 1 district there are 15 sulphate of ammonia works, in which 2130 tons of sulphate were manufactured last year. Operations were much restricted in many of the smaller works. In some cases the scarcity of water led to a decrease in the quantity of liquor produced; and in one instance the liquor was used for direct application to the land in the vicinity—thus entirely stopping the manufacture of the sulphate. The use of oxide of iron purifiers continues to be extended; and in three instances these were introduced during the past year, and are working satisfactorily. A further improvement to be noted in two works is the substitution of continuous stills heated by steam in place of the older form of still in which each charge of liquor is heated and boiled off separately. The newer mode of working lessens considerably the proportion of steam driven off during the distillation, and renders the evolution of the noxious gases more regular and constant; thus facilitating the cooling and subsequent treatment of these gases. The general average acidity of chimney smoke in works of this class, where the escaping gases continue to be burned, was 0.26 grains of sulphuric anhydride per cubic foot. This figure, Mr. Curphey remarks, is very low, but is not, however, a proper measure of the total quantity of sulphurous acid driven into the air from these works. Repeatedly, distinct quantities of ammonia have been observed to pass away from the saturators with the waste gases. This ammonia combining with and neutralizing an equivalent quantity of sulphurous acid prevents this combined sulphurous acid from increasing the acidity of the smoke.

The number of sulphate of ammonia works in No. 2 district is not given; but it is stated that among the 137 separate processes under inspection, 29 relate to sulphate making, and 1 is for the treatment of gas liquor. Particulars are furnished by the Inspector of the various alterations and improvements carried out last year in the works coming within his purview; and in all cases the effect was the reduction of nuisance. In one works, instead of burning the sulphuretted hydrogen, the following plant was erected and connected with the sulphate of ammonia apparatus put up during the latter part of the previous year:—Two condensers packed with coke 14 feet high and 3 feet in diameter, the first of which is supplied with a constant stream of water; and two oxide purifiers 7 ft. by 7 ft. 6 in. by 5 ft. 6 in. The distance beyond this through which gas has to travel in 6-inch pipes is 10.2 feet. The improvement in sulphate of ammonia works mentioned by Mr. Smith in his previous report continued last year, both as regards the condition of the plant and in the method of dealing with the foul gases evolved during the manufacture of the salt. The quantity of sulphate made in the course of the past year at gas-works and at works where the tar and liquor collected from gas-works is employed was 2306 tons, whilst at coke-works 311 tons were made; making a total for the entire district of 2617 tons, which is an increase of 233 tons over 1886. Mr. Smith states that after a lengthened trial, oxide of iron purifiers have undoubtedly proved themselves the most efficient vehicle for the removal of sulphuretted hydrogen from the foul gases evolved from sulphate plant at work. For numerous reasons any attempt to fix an arbitrary limit to the size of purifiers on the lines of the weekly make of sulphate is impossible. In the first place, in no two gas-works (or, indeed, in the same works for any length of time) is the quality of the foul gas constant as regards the percentage of sulphuretted hydrogen; neither are the various oxides employed at different works the same as regards their absorbent or decomposing power—some qualities of oxide becoming much more rapidly spent than others. Then, again, the oxide rapidly loses power after each revivification. The more sulphur it contains, the less room is there for active oxide. He adds: "Putting the above on one side, one great reason I have for not attempting to have the purifiers of any particular design or size is that the majority of plants are built at gas-works long after the works have been erected. They are necessarily, therefore, built to fit the space at disposal—the purifiers having to follow suite. It then becomes a question to the manager as to which is most valuable, space or labour; and the latter, as regards the shifting of small quantities of oxide, counts for little. The usual and most convenient size, irrespective of make per week, is, I find about 30 cubic yards of oxide, arranged so as to allow the gas to pass through a layer of oxide 3 feet thick (bricks say 5 ft. by 5 ft. by 4 ft.). I find that it is always best to have two purifiers, using them alternately; or having one in reserve in case of accidents. They should be protected from rain, but not closely covered; and provided the oxide is kept dry, I find one layer an improvement on two or three, also a saving on the more costly construction on account of increase in number of grids required."

In No. 3 district there are 27 sulphate of ammonia works and 3 gas-liquor works—an increase of 3 of the former works since the previous report. The gas-liquor works gave little or no trouble last year; there being no escapes of sulphuretted hydrogen therefrom. With regard to the sulphate of ammonia works, Mr. Ballard says: "There is a tendency on the part of these works to change from the intermittent to the continuous process of distillation, which is a satisfactory step to be able to report, since the purifiers are less liable to be suddenly overtaxed, and the risk arising from the escape of sulphuretted hydrogen is correspondingly diminished. With a few exceptions, this class of works has been found to be in a fairly satisfactory condition. There is yet some room for improvement by the general adoption of oxide purifiers in place of dealing with the sulphuretted hydrogen by burning it." He gives particulars of the system of distillation adopted in 22 gas-works in his district. In 15 the process is intermittent; in the rest continuous. In six of the works where the intermittent process is carried on, the sulphuretted hydrogen evolved is burnt; in the other cases it is passed through oxide purifiers. In only

one instance where the continuous process is in use is the above-named impurity got rid of by burning. The quantity of coal carbonized last year in the 22 works was 184,065 tons; the amount of sulphate produced, 1830 tons—the total for the entire district being 2592 tons. In the Widnes sub-district, the manufacture of sulphate of ammonia last year did not call for any remark.

With regard to the East Lancashire and Yorkshire district (No. 4), Mr. R. Forbes Carpenter has rather a long story to tell. Seven additional works were registered last year; but, owing to the transference of three old works to No. 5 district, the net increase was only four. Of the new works, two manufacture liquid ammonia, the remainder sulphate of ammonia. About 19,000 tons of the latter commodity were made in the district in 1887. Increase has occurred at most gas-works; but in coal carbonizing works less was produced. As to works manufacturing sulphate, Mr. Carpenter says it is satisfactory to be able to report that none now make use of the combustion method of dealing with the foul gases from the saturator. By "combustion method" is meant simply burning the sulphuretted hydrogen in the previously dried gases to sulphur dioxide, and passing the products direct to the chimney. In seven works the gases after combustion form part of the sulphur supply to the vitriol chambers; three works are using the Claus process of limited combustion for the recovery of sulphur; and the remaining works make use of hydrated oxide of iron purifiers. The first-mentioned method, we are told, gives great satisfaction; but a little more watchfulness is required of the chamber operations at the starting and stopping of the sulphate plant. It is perhaps necessary to observe that this method (and the same remark applies to the Claus process) is only practicable where the supply of sulphuretted hydrogen is rendered as regular as possible by the use of the Coffey still. Greater experience has been gained of the Claus process during the year, through its introduction at two large sulphate-works. At one the proprietor was desirous of commencing operations without the use of the final alkaline wash-tower, but with a final catch oxide purifier, intending to work with a supply of air on the under side of that necessary for perfect re-action, hoping thereby to have no sulphur dioxide, but only sulphuretted hydrogen to deal with. He has found, however, that the presence of a very small quantity of the former impurity is sufficient to render the catch purifier quite ineffective; and, moreover, that the fine sulphur dust carried forward with the gases to the oxide, and washed out with the sulphur dioxide in the alkaline wash-tower, where this precedes the purifier, acts as a serious clog, causing back pressure on the saturators, and necessitates the daily turning over of the oxide. At the other works, where operations with the process only commenced at the close of the year, this defect has been avoided (and at the other remedied), and the plant was found to be quite efficient for its work. The form of kiln or decomposer, however, seems open to criticism; the gases passing through horizontally. The best form seems to be that in which the gases work downwards through the active material (in manner similar to that found so successful in the Deacon process. There is also this great advantage—that on the starting of the process after a long stoppage, if the material is at first sluggish, and will not rapidly heat, it becomes a very easy matter to scatter a little fresh hydrated oxide on the surface of the old, and activity will rapidly ensue. In this process, as in some other analogous ones, success depends on the regularity and constancy of the supply of gases involved in the re-action. It takes a day or two to reach the steady average of most favourable working conditions; and, unfortunately for the process, the week-end break comes to interrupt conditions when perhaps they are most favourable. At another works, 48 tons of sulphur were recovered last year; the average total acidity as sulphur trioxide at the exit of the collecting chambers was 1.90 grains. On two occasions when tested, sulphuretted hydrogen was present in mere traces; one of these being the occasion when the lowest amount (0.35 grain) of sulphur trioxide was found; on only one occasion was the amount of acidity above 4 grains of sulphur trioxide. Mr. Carpenter thinks that experience certainly confirms the statement made in a previous report of sulphur trioxide, that when the process is not working well in the decomposer the escape of both sulphurous acid and sulphuretted hydrogen is high.

Mr. Carpenter further observes: "As regards the working of oxide purifiers and their best size and construction, I have in previous reports made some remarks on the subject. As regards the construction of the purifier, doubtless cast iron is the best material; but brick purifiers can be easily made gas-tight by building them with a 1 inch cavity wall and filling in with melted pitch—grouting the bottom with the same. If revivification *in situ* is practised, the cavity should be separated by a 9-inch, not 4½-inch, thickness from the oxide (in the latter case I have seen the pitch disappear slowly into the ground). But my experience certainly leads me to distrust the efficiency of ordinary brick and cement built purifiers. Two tiers of grids are more efficient per given quantity of oxide than one tier, probably three are more efficient than two. Certainly the gases have a better chance of even distribution, and do not tend so readily to choose one point of less resistance. Large superficies with only one set of grids may be overdone, and become unmanageable; 200 superficial feet is as large as my experience shows to be desirable for use at one time. All purifiers should be open; revivification *in situ* being carried on by reversal of draught through the oxide by means of one three-way valve. It is impossible to give a standard size of purifier for a given quantity of gas liquor. This latter varies greatly in composition, especially in the percentage of ammonia combined with sulphur, because the method of scrubbing varies in different gas-works, as well as the composition of the coal used. Again, the treatment of the gas liquor is the principal factor determining the size of the purifier. If the simple distillation method is pursued, provision has to be made for the evolution and treatment of the whole of the sulphuretted hydrogen in the early stage of the batch, instead of its evolution being equally spread over the time of working, as in the Coffey-still arrangement. In the construction of condensing plant, particular attention should be paid to the point named in the previous year's report—viz., the removal of condensed water from the system at the point where the gases are hottest. Further experiment has confirmed the figures there given, that, where taken off at the cooler end, the water may carry away 5 per cent. of the sulphuretted hydrogen in solution. This, of course, leads strongly to the condemnation of the method (formerly in use, but no longer so, in two works in this district) of cooling the gases by an internal spray of cold water, where the water finds its way subsequently into the sewers. Not only will the volume be much larger, but every gallon will carry away more sulphuretted hydrogen than is carried away under the system first mentioned. The quantity removed in solution, indeed, bears such a considerable proportion to the whole that the method can no longer be classed under the head of 'the best practicable means' of dealing with this noxious gas. If, however, the spray is used in quantity only barely sufficient to condense the whole of the steam present, and the plant is so arranged that the products of condensation flow through the apparatus in a reverse current to that of the hot gases issuing from the saturator—care being observed to take off the water of condensation and that from the spray at the hottest possible point, so that they issue from

the seal at boiling temperature—the objection to the internal use of water in the condensers is minimized. Care must be taken to cool this so-called 'devil water' before it runs into sewers. The peculiar offensive and characteristic odour is due to the presence of pyridine, now in demand in Germany for addition to alcohol used for manufacturing purposes, to prevent any being drunk by the workmen employed; 'methylating' the alcohol having proved quite inefficient for the end. Further cases have been noticed during the year of failure of oxide to revivify, and of oxidation to ferric and ferrous sulphates. This latter phenomenon has shown itself almost exclusively, I believe, in works working on the simple distillation method, to which class, however, the first-named difficulty has not been confined.

Further extracts from the District Inspectors' reports, as well as from the report for Scotland, are reserved till next week.

SERIOUS ALLEGATIONS AS TO THE HALIFAX GAS COAL CONTRACTS.

The following correspondence has, we understand, passed between the Town Clerk of Halifax (Mr. Keighley Walton) and the parties whose names are given below, and its publication was last Friday authorized by the Gas Committee of the Corporation; the Committee at the same time deciding to recommend the Town Council to take Counsel's opinion on the matter:—

CORRESPONDENCE BETWEEN MR. ELLIS LEVER AND THE TOWN CLERK.

No. 1.—*Mr. Ellis Lever to the Town Clerk.*

May 22, 1888.—I am in receipt of your circular letter dated the 19th inst., informing me that my firm's offer of cannel has been declined by the Gas-Works Committee, which, with the information in my possession, does not surprise me. In the interests of fair and honourable trading, as also of the ratepayers and gas consumers of Halifax, I must ask you for an appointment to enable me to show you how the Committee have been dealt with in the past.

No. 2.—*The Town Clerk to Mr. Ellis Lever.*

May 24, 1888.—Absence from home has prevented an earlier reply to your letter of the 22nd inst. I shall be at the office all next week, and shall be glad to see you any time between ten and five o'clock.

[No further communication has been received from Mr. Lever, neither has he called to see the Town Clerk.]

CORRESPONDENCE BETWEEN THE TOWN CLERK AND THE EDITOR OF THE "PALL MALL GAZETTE."

No. 3.—*The Town Clerk to the Editor.*

June 22, 1888.—Corrupt Practices in the Gas Industry.—I am desired by the Mayor of this borough to draw your attention to an article headed as above in your issue of the 7th inst., and which concludes with the following sentence—viz., "We should hear shortly of disclosures in Halifax, if the parties concerned dare to court inquiry." This article has been copied into a local paper called the *Halifax Times* (a copy of which is sent herewith). The Editor, in commenting on your article, alleges that it is a distinct charge of corruption against the Gas Committee of the Halifax Corporation, or their servants, or both, and they are dared to court inquiry; and very properly ends by stating that neither the Corporation, nor Committee, nor their servants, can afford to remain silent. The allegation is now a matter of the greatest interest in the town, and the general opinion is that the question should be sifted to the bottom. In the first place, I should be glad to know from you whether the complexion put upon your article is a correct one, and if so whether you will assist the Mayor to get to the bottom of the matter. The Corporation court the earliest and the fullest inquiry.

The following appeared in the *Pall Mall Gazette* of June 7:—

CORRUPT PRACTICES IN THE GAS INDUSTRY.—The existence of corruption in the gas industry has been sufficiently demonstrated by the notorious Salford case; but whether it is the laggard way in which that criminal has been treated, or that the evil is too deeply seated, it does not appear that there has been any change for the better. Similar charges have been brought against officials in other towns; but it is left to private individuals to run the risk of actions for criminal libel. The surprising thing is that the ratepayers do not make a stir and demand an inquiry, for certainly a Royal Commission would disclose much grosser corruption than that which is astonishing the public in the case of the Metropolitan Board of Works. We have just received from Mr. George Bray, of Leeds, a pamphlet in which he deals with this evil, and in which he expresses the opinion that "corruption in the gas industry has been largely fostered by the policy pursued by the Council of The Gas Institute." Mr. Bray's fight with that body has been a protracted one, but it is not yet over, as the Council intend to propose, at the annual meeting of the Institute on June 12, to expel him unless he withdraws his charges of malpractices against some of the officials and Mr. George T. Livesey, a Past-President of the Institute, and now Chairman of the South Metropolitan Gas Company. But why does the Institute not insist upon an inquiry into the charges brought against its officials? After the grave disclosures in other quarters, the Institute will not act wisely in taking this method of silencing the accuser. Mr. Hunter was remarkably virtuous when in the witness-box; but when in the dock he is ready to make restitution to the extent, it is understood, of £25,000. We should hear shortly of disclosures in Halifax, if the parties concerned dare to court inquiry.

No. 4.—*The Editor to the Town Clerk.*

June 23, 1888.—I beg to acknowledge the receipt of your letter of the 22nd inst., and to say that I do not propose at present to add anything to the note to which you call my attention. At the same time I must ask you not to draw from this reply the conclusion that I am prepared to become responsible for constructions which other persons or papers may have placed on a note published in the *Pall Mall Gazette*.

No. 5.—*The Town Clerk to the Editor.*

June 27, 1888.—Your letter of the 23rd, in reply to mine of the 22nd inst., was only received here yesterday, and is not satisfactory. The article in your paper, headed "Corrupt Practices in the Gas Industry," first refers to the notorious Salford case, then states that similar charges have been brought against officials in other towns, and ends by stating that we should hear shortly of disclosures in Halifax, if the parties concerned dare to court inquiry. The gas-works in Halifax are the property of the Corporation, and are managed by them and their officials. They therefore can be the only persons meant by the "parties concerned." This is the universal construction put upon your words; and, indeed, it seems to be the only natural construction that can be placed upon them. The Corporation, as stated in my letter, accept the challenge made by you; and not only dare, but do court the fullest inquiry. Your letter seems to me to repudiate the construction put upon the words in the *Pall Mall Gazette* by the public and the press, and to shirk the responsibility attaching to the words used. The Gas Committee will meet on Friday next; and I shall be glad to be informed whether your remarks had reference to any member of the Corporation or their officials; and if they had not, whether you are willing to publish the correspondence in the *Pall Mall Gazette*.

No. 6.—*The Editor to the Town Clerk.*

June 28, 1888.—I beg to acknowledge your letter of the 27th inst., and have only to repeat that I do not at present propose to add anything to

the note in question. I would have no objection to publishing the material portion of the correspondence, if you so desire.

CORRESPONDENCE BETWEEN MR. T. FOX, OF THE SILKESTONE COAL COMPANY, AND THE TOWN CLERK.

No. 7.—*From Mr. T. Fox to the Town Clerk.*

June 2, 1888.—I wish to know why my firm were not asked to send sample trucks of gas coal, as resolved by the Committee. Our tender has been declined without giving the coal a trial; and I am confident the material we offered is worth far more than some of that you have purchased. It is not in the interests of the Corporation that the ratepayers should not have the best value for their money; and the Halifax Corporation will be well advised to inquire into the charge I now make before putting their seal to any contracts. I am informed, on very good authority, that one man has an interest, directly or indirectly, in many contracts with the Gas Department of the Corporation of Halifax; and it would be well that this matter should be sifted to the bottom. Halifax cannot desire a repetition of the Salford scandal.

No. 8.—*Telegram from the Town Clerk to Mr. Fox.*

Council meet to-night to seal contracts. Am I to read your letter to the Council?

No. 9.—*Telegram from Mr. Fox to the Town Clerk.*

Just received your yesterday's wire. See or write to-morrow.

No. 10.—*From Mr. Fox to the Town Clerk.*

June 8, 1888.—I regret that when your telegram arrived on Wednesday I was in London; and as I did not return until late last evening I was not able to reply. I shall be glad to hear whether your Council have confirmed the action of the Gas Committee with reference to the gas contracts, and, on hearing, will communicate further with you.

No. 11.—*The Town Clerk to Mr. Fox.*

June 9, 1888.—In reply to your letter of yesterday's date, I beg to state that the Council on Wednesday last confirmed the minutes and proceedings of the Gas-Works Committee with reference to the gas contracts.

No. 12.—*The Town Clerk to Mr. Fox.*

June 18, 1888.—I have read your letters to the Gas Committee, and am instructed to state that they are prepared to give you every opportunity of proving the charge referred to in yours of the 2nd inst., and quite agree with you that the matter should be sifted to the bottom. I assure you Halifax does not desire a repetition of the Salford scandal. In your last letter, dated the 8th inst. (now ten days ago), you stated that you would communicate further with me; and I am very much surprised that I have not heard from you since. The matter has now become one of public comment; and the Gas Committee are anxious that the charges should be inquired into without any unnecessary delay, and court the fullest and earliest inquiry.

No. 13.—*The Town Clerk to Mr. Fox.*

June 21, 1888.—I am greatly surprised at not receiving any reply to my two last letters. Your earliest attention is specially requested.

No. 14.—*Mr. Fox to the Town Clerk.*

June 23, 1888.—I am in receipt of your two favours of the 18th and 21st inst., and have not been able to reply ere now, as I have been laid up with illness for over a week. Before going into details, please reply to the inquiry contained in the first paragraph of my letter dated the 2nd inst.

No. 15.—*From the Town Clerk to Mr. Fox.*

June 26, 1888.—In reply to yours of the 23rd inst., I beg to state that the Committee did not resolve to ask you to send a sample truck of gas coal, as assumed in your letter of the 2nd inst.

No. 16.—*From Mr. Fox to the Town Clerk.*

June 26, 1888.—Referring to your favours dated the 18th and 21st inst., I may further say that as your Council confirmed the purchase of the Gas Committee, notwithstanding my letter of the 2nd inst., I am not now disposed to furnish you with any specific information unless I receive a complete indemnity against all costs in the event of my charges being proved, which they can be.

No. 17.—*From the Town Clerk to Mr. Fox.*

June 27, 1888.—Before I reply to yours of yesterday's date, will you be good enough to state by return whether the one man referred to in yours of the 2nd inst., as being interested in contracts with the Gas Department, is a member of the Halifax Town Council or a servant of the Corporation, or neither one nor the other. The Gas Committee meet on Friday forenoon; and I shall feel obliged by your answer before then, as I shall lay the correspondence before them on that day.

No. 18.—*From Mr. Fox to the Town Clerk.*

June 28, 1888.—Your letter of the 27th inst. to hand this morning. In reply, I beg to refer you to my letter of the 26th inst., which I now confirm. Beyond this I cannot go; and I think you ought not to ask more than that. On receiving a full indemnity, I am prepared to give you the information you ask.

WEST HARTLEPOOL GAS SUPPLY.—The extension of works which is now in progress at West Hartlepool will, with the winter, largely increase the consumption of gas. A new shipbuilding yard is commencing; and new steel-works will be brought into operation this month. Other extensions going on must very soon largely increase the need for illuminants, as well as foster their use by the larger population being brought together.

FENTON LOCAL BOARD GAS SUPPLY.—At the last meeting of the Fenton Local Board, the Gas Committee reported that during the year ended March 25, 37,781,000 cubic feet of gas were manufactured, which was an increase of 2,611,000 cubic feet as compared with the previous twelve months. The gross receipts were £5866 5s. 7d., an increase of £532 14s. 8d.; and the working expenses £3307 9s. 8d., or an increase of £157 0s. 11d. The net profit was £2558 16s. 1d.; being an increase of £375 13s. 9d.

POYNTON WATER SUPPLY.—During and since the excessive drought of last year, the village of Poynton, in common with a great many other places, has been very short of water, and at present the main supply from springs in the neighbourhood is very nearly exhausted. Lord Vernon, however, has just added a new supply, which will place Poynton in a very much better position than it has ever been in before, and will be a great boon to the inhabitants. The main supply of water is collected from springs near Poynton Towers into a covered reservoir, and is distributed to the village by means of pipes, which in some cases deliver direct to the houses, and in others to stand-pipes placed at various points for the convenience of the inhabitants. Lord Vernon has now sunk a well 84 feet in depth to the new red sandstone, about half a mile from the reservoir, and is arranging to pump the water, which has been analyzed by Dr. Voelcker, of London, and pronounced to be of most excellent quality, and convey it in pipes to the reservoir, and so supplement the present service. The supply of water from the new red sandstone is practically inexhaustible; and therefore the inhabitants of Poynton may be congratulated on being relieved from a very unpleasant situation. The pumping machinery is worked by electricity.

THE PROPOSED PURCHASE OF THE EDINBURGH AND LEITH GAS-WORKS BY THE CORPORATIONS.

AGREEMENT WITH THE EDINBURGH AND LEITH COMPANY.

Last Friday night the negotiations between the Edinburgh and Leith Gas Company and the Edinburgh and Leith Corporations, for the transfer of the Company's undertaking to these Authorities, were brought to a termination by the adoption of an agreement which is regarded as satisfactory by both sides. After a long period, in which the subject was handled in a very apathetic manner, active operations began on the 26th of May last, and were kept up without intermission until their happy conclusion at the end of the past week. A conference was held in the offices of the Company on the 21st ult., between representatives of the two bodies, at which a draft agreement was adopted, embodying the terms upon which the concern was to be taken over, provided that a favourable report as to the Company's position was obtained. It was agreed that the books of the Company should be examined by Mr. Alfred Lass, F.C.A., and that the works and plant should be inspected by Mr. George Livesey; that these two gentlemen should then report jointly whether or not the proposed bargain was fair and reasonable to both parties; and that if it were, the agreement should at once come in force, but that if it were not the agreement should be considered as never having existed—the Corporations being precluded from referring to or founding upon it, as well as from putting either Mr. Lass or Mr. Livesey into the witness-box to be questioned on any information they obtained in the course of their investigations. On these conditions Mr. Lass examined the Company's books in their office on Monday, Tuesday, and Wednesday last week; and Mr. Livesey inspected the works on Thursday. Their report, which was submitted on Thursday night, was to the effect that, in their opinion, the proposed bargain was fair and reasonable to both the contracting parties. On Friday the agreement was signed and sealed; and was then made public. The terms of the purchase are these: The Corporations are to acquire the whole undertaking of the Company, including all property and assets—heritable and moveable, real and personal—of whatever kind, and wheresoever situated; but there are to be excepted from the undertaking all cash in hand, including the sum of £12,500 lent to the Leith Dock Commission, £723 10s. 6d. invested in Edinburgh Water Annuities, and the value of the Company's property in St. Andrew's Square, standing in the books of the Company at £8500—together, £21,723 10s. 6d. The agreement proceeds thus: The Corporations shall pay to the Company as the price of the undertaking (1) the sum of £11,000; (2) annuities, as hereinafter specified, to the amount of £14,000 per annum, equal to 9½ per cent. on the paid-up share capital; and (3) the value of all stocks as may be agreed on or as shall be fixed by arbiters mutually chosen by the Corporations on the one part and the Company on the other part, or by an oversman named by such arbiters. The date of transfer of the undertaking shall be the 1st day of August, 1888; and the money price shall be payable upon that date, and the annuity certificates shall be delivered on that date, or as soon after as may be. Until the said 1st day of August, 1888, the Company shall, as hereinafter mentioned, continue to carry on and manage their undertaking at their own discretion as heretofore, and shall continue to keep the works in good working order, and shall also continue to keep proper accounts. The Company shall have right to all the revenue and profit derived from, or earned by the undertaking to the date of transfer, and shall pay all the revenue debts and liabilities up to such date. The Company shall not be entitled, in so carrying on the undertaking, to enter into any contract extending for a longer period than one year beyond the 1st day of August, 1888, except with the consent in writing of the Corporations, or, after the constitution by Parliament of the intended Commission or Trust, with the consent in writing of the Commissioners or Trustees. The Corporations at the date of the transfer shall take over and pay the mortgage or debenture debts of the Company, amounting in all to the sum of £20,000, and the bank loan debt of the Company, amounting to the sum of £11,700, in so far as the bank loan debt has been applied to capital expenditure. The Company shall not, as from the date of this agreement, expend any sum or sums on capital account without the sanction in writing of the Corporations or of persons appointed by them to dispose of the matter, or, after the constitution by Parliament of the intended Commission or Trust, without the consent in writing of the Commissioners or Trustees; and all such capital expenditure so sanctioned shall be paid by the Corporations in addition to the price. Provided always that the Company, on payment to them of any such sums which may be so expended on capital account, shall be bound to exhibit vouchers or discharges or other evidence for the same. The Corporations shall, subject to the previously obtained sanction as to capital expenditure provided for herein, pay and fulfil the whole debts and liabilities of the Company outstanding at the 1st day of August, 1888, and shall free and relieve the Company therefrom, save and except debts and obligations undertaken or incurred by the Company on revenue account; among such debts and liabilities to be paid and fulfilled by the Corporations to be included pensions and retiring allowances to officers or employees of the Company. Provided always that the same pensions shall be payable only during the respective lives of such officers or employees whose names and the amount of pensions payable to each are communicated in writing by the Company to the Corporation simultaneously with the execution of this agreement, and the whole amount shall not exceed the sum of £1150 at the date when such pensions shall begin to be payable by the Corporations; and provided, further, that it shall be lawful for the Corporations to continue the Manager of the Company in an office similar to that which he now holds, or to appoint him to such other office as may be mutually agreed to, and to appoint the Treasurer and Statutory Clerk of the Company to such offices as the Commissioners may see fit, and that, while the officials respectively hold their offices, the retiring allowances provided for them respectively—amounting in all, conformably to the list, to £965—shall be imputed towards the salaries attached to such offices respectively. Provided always that so long as the Commissioners shall be willing to employ the said Manager, Treasurer, or Statutory Clerk, or any of them, in the manner above provided, and at salaries not less than presently paid to any such officials, the said officials shall not—in the event of their voluntarily leaving the service of the Commissioners for the purpose of entering another service at higher remuneration in all than the salaries they may at the time be respectively receiving—he be entitled to claim such pensions. It is provided that the annuities are to be terminable at 28½ years' purchase after the lapse of 20 years, similarly to those which are to be paid to the Edinburgh Company. Provision is also made for the insertion of clauses in the Corporations' Bill giving effect to the foregoing agreement and the withdrawal of the opposition of the Company to the Bill. The total annual charge against the Corporations will be £18,809, under the agreement, made up as follows:—£14,000 annuities; interest upon £11,000 of cash to be paid to the Company; on £31,700 of mortgage and loan debt; on £20,000 to pay for stocks and stores, assuming that the Corporations will be able to borrow at 3½ per cent.; 1 per cent. of sinking fund on money borrowed, £620; and ½ per cent. upon the capitalized value of the annuities, £1995. The profits earned by the Leith Company for 1887 were £23,300; for 1888, about £27,000.

Following upon the agreement, representatives of the Corporations and of the Gas Company left Edinburgh on Saturday morning for London, to adjust the necessary clauses, so as to be ready for the hearing of the Corporations' Bill before the House of Commons Committee, which was originally fixed for to-morrow, but now stands in the paper for Thursday.

BIRMINGHAM CORPORATION GAS SUPPLY.

REPORT BY THE GAS COMMITTEE.

At the Meeting of the Birmingham Town Council to-day, the Gas Committee will present a report on the progress of the gas undertaking of the Corporation. The following is an abstract of the document:—

The report opens with a reference to the death of Alderman Hart, and to the appointment of Mr. Bishop as his successor in the chairmanship of the Committee. A resolution was passed recording their sorrow at his loss, their sympathy with his family in their bereavement, and their sense of the ability and zeal which he had devoted to the work of the Gas Department. Another personal matter mentioned in the report is the resignation of Mr. J. Haynes of his appointment as Fittings Superintendent, in order to take a similar position in the Liverpool Gas-Fittings Company, Limited; and the selection of Mr. S. R. Barrett to succeed him.

The Committee have informed the gas consumers within the Quinton district that the additional charge of 6d. per 1000 cubic feet for gas supplied to them has been withdrawn, as from the March reading of the meters. The question of the right of the Corporation to continue this charge, which amounts only to a small sum per annum, came under consideration on an application from a resident in the district for a supply of gas. The Town Clerk has advised that a new consumer is entitled, under the Corporation (Consolidation) Act, to a supply at the price charged in the remainder of the area, and is not bound by the agreement made with the consumers when the mains were extended to this district. The Committee have therefore thought it desirable, although the consumption in the district has not reached the quantity at which the agreement provided that the additional charge should terminate, to abolish this distinctive charge.

The Committee have been in correspondence with the Bilston Gas Company as to the supply by that Company of a small portion of the district of Moxley, in the parish of Darlaston, within the Corporation area. They have ascertained that the Company claim that this supply forms a portion of the sale to them by the Birmingham and Staffordshire Gas Company of the supply in Bilston. The Company are, however, unable to produce the agreement under which the sale is claimed to have been made; and a reference to the minutes of the Staffordshire Gas Company, recording the transfer of the Bilston supply, does not support the claim. The Town Clerk having advised that the rights of consumers in the respective areas of supply as defined by the Acts of Parliament cannot be set aside by an agreement, the Committee have informed the Company that they will comply with the requirements of the Corporation Act, which includes the whole of the parish of Darlaston, and will, on the application of the consumers in the area in dispute, supply them with gas.

A memorial has been received from the workmen at the Windsor Street station other than those employed in carbonization, asking for a holiday or holidays similar to those given to the workmen in other departments of the Corporation. The Committee not having complete information as to the practice in other departments, and being reluctant to take any action which might affect those departments, recommend that the memorial be referred to the General Purposes Committee for the purpose of obtaining information as to the practice followed in the other departments as regards Bank Holidays, and of determining the principle to be observed in this respect throughout the Corporation as regards the staff paid by salaries or fixed wages and the men paid by time. A memorial has also been received by the Committee from the workmen employed in carbonization at the various works of the department, asking for "one week's holiday during the summer months of each year, under the same conditions as the employees and officials under the Corporation generally." The Committee recommend that this memorial should also be referred to the General Purposes Committee, on the ground that the Gas Committee cannot deal with the prayer of the memorialists in any direction without affecting the position of other Committees, especially having regard to the recent vote of the Council on the subject.

The Local Authorities of Aston and Balsall Heath having undertaken to light and extinguish lamps in courts without charge, the charge for gas to such lamps in these districts has been reduced to 1s. 1d. per 1000 cubic feet; and an arrangement has been made with these Authorities that they shall undertake the maintenance of such lamps on the usual terms.

The Cherterton Coal and Iron Company, Limited, having failed to continue deliveries of coal to the Adderley Street works under their contract, and having since gone into liquidation, coal has been purchased against the Company under its unexpired contracts, to June 30, 1889, both for the Adderley Street and Windsor Street works; and the amount of the loss on these repurchases has been deducted from the amount owing by the Corporation to the Company.

A contract has been made with Messrs. L. Demuth and Co. for the sale to them of the whole of the tar produced at the works of the Corporation from the 1st inst. The contract is for ten years; but it is terminable, in the event of dispute arising out of the periodical revision of prices for which it provides. Under this contract there will be a considerable increase in the income derived from this residual during the coming year.

Having regard to the scarcity of coke in this district in the present summer months, and to the higher prices offered for it by large buyers under contract, the Committee advanced the prices for all contracts from March 31, and for the retail trade from the 14th of May. The quantity of coke in stock on June 21 was 763 tons, as against 19,124 tons at the corresponding period of last year.

The quantity of gas sold in the quarter ended March 31 last was 1,185,884,900 cubic feet, as against 1,144,240,000 cubic feet in the corresponding quarter of 1887; being an increase of 41,644,900 cubic feet, or nearly 3½ per cent. There were 52 official tests of the illuminating power of the gas made during the quarter ended March 31; the highest being 17·89 candles, the lowest 16·97 candles, and the average 17·35 candles, or 2·35 candles in excess of the parliamentary standard.

VISIT OF THE MANCHESTER CORPORATION TO THE THIRLMERE WORKS.—Last Thursday the members of the Manchester Corporation visited the works now being carried out in the Lake district for the conveyance of the Thirlmere water to Manchester. The present area of the lake is 328½ acres. If it is raised 50 feet, as sanctioned by Parliament, the area will be increased to 793 acres, and the capacity to 8,130,686,693 gallons. It is, however, in contemplation at present to raise the level only 30 feet. In the pipe-laying there are 13½ miles of tunnelling, 37 miles of cut-and-cover, and 44 miles of syphon pipes; the total length from Thirlmere to Prestwich being 95½ miles. The party stayed for the night at Grasmere, and on Friday completed their inspection of the works; returning to Manchester from Kendal.

IMPORTANT SALES OF GAS SHARES.

At the Mart, Tokenhouse Yard, last Friday, Messrs. Thurgood and Martin offered for sale (by order of the Royal College of Surgeons of England), £24,780 of stock, producing dividends at the rates of 10, 7, and 6 per cent. per annum, and new 375 £6 (fully paid) shares, earning a dividend of 7 per cent., in the Crystal Palace District Gas Company. As notified in the JOURNAL last week, under the will of the late Sir Erasmus Wilson, the bulk of his property has passed to the Royal College of Surgeons, including his holding in this Company, of which for many years he was Chairman. The auctioneer (Mr. Howard Martin), in the course of a few preliminary remarks, said he had been told that they had taken a bold step in offering so large a quantity of this stock and shares in the Crystal Palace Gas Company at one time; but he had so much confidence in the Company that he did not think this would make any difference in the price. He then remarked upon the prosperity and prudent management of the concern during past years; and quoted some statistics from the speech of the Chairman at the last half-yearly meeting to show the progress made during the past ten years. The whole of the stock and shares were sold *cum div.* The first lots consisted of £6325 of 10 per cent. ordinary stock, disposed of as follows:—£500 sold at £213 per cent.; £500, at £211; £1000, at £209; £500, at £208; £2500, at £207 10s.; and £1325, at £207. The second parcel comprised £13,585 of 7 per cent. ordinary stock, which fetched the following prices:—£5000, £154 10s. per cent.; £1500, £154; £1000, £151; £500, £148; £1000, £147; £1000, £146 10s.; £3585, £146. The final portion of stock was £4870 of 6 per cent. preference stock; and it sold as follows:—£120 at £126 per cent.; £2750 at £125 10s.; £750 at £125; and £1250 at £123 10s. The 375 £6 new fully paid ordinary shares were all readily disposed of at the uniform price of £8 17s. 6d. per share.

On Tuesday last, Messrs. Baxter, Payne, and Lepper, sold the following gas shares, at the Mart, Tokenhouse Yard:—Fifteen £10 fully paid-up shares in the Crays Gas Company, now paying 10 per cent., at £18 15s. per share; and 20 similar shares, at £18 5s. Forty £10 new ordinary shares in the Croydon Commercial Gas and Coke Company realized £20 15s. each; 70 similar shares, £20 17s. 6d.; and 10, £20 18s. A parcel of 25 £5 shares in the same Company produced £11 each; and £300 of the ordinary "B" stock in the South Metropolitan Gas Company, £720.

BUXTON LOCAL BOARD GAS SUPPLY.

The Gas Engineer of the Buxton Local Board (Mr. George Smedley) has presented to the Gas Committee the following report on the gas production during the year ending the 25th of March last:—The gas produced during the year was 45,303,100 cubic feet, and the quantity distributed 43,283,300 cubic feet, composed as follows:—Consumers' meters, 40,516,700 feet; public lamps, 3,211,100 feet; works, offices, clock, &c., 1,036,000 feet—making the gas not accounted for 2,019,800 cubic feet, or at the rate of 4.458 per cent. The coal carbonized was 2406 tons 18 cwt.; the cannel, 1905 tons 3 cwt.—total, 4312 tons 1 cwt. The average production was 10,506 cubic feet per ton; and the gas distributed, 10,151 cubic feet. The amount booked in the rental is £6454 6s. 4d.; estimated for public lamps, £479 12s. 11d.—total, £6933 19s. 3d. This makes the average return per ton of coal £1 12s. 1½d. The average illuminating power of the gas was 20.33 candles. The cost of gas into the holders, after deducting the value of the residuals, was 10.208d. per 1000 cubic feet. The increase in the quantity of gas produced in the year, as compared with the year 1886-7, was 680,500 cubic feet; in that distributed, 2,029,000 cubic feet; and in the cash, £226 5s. The net cost into the holders was 2.409d. per 1000 feet less than in the year 1886-7. The coal cost £2481 3s.; being £33 8s. 5d. below 1887. There were 106 meters fixed and 90 removed during the year; being an increase of 16. The wages paid amounted to £1343 19s. 11d., which is £51 16s. 9d. less than in the preceding year, and averages 7.188d. per 1000 cubic feet, including production, distribution, repairs, fittings, &c.

THE GAS SUPPLY OF BIRKENSHAW AND GOMERSAL.

RIVAL GAS COMPANIES AND THEIR DISTRICTS.

The following article, dealing with the position of the gas supply of Birkenshaw and Gomersal, recently appeared in the *Bradford Observer*:—For many years the majority of people at Birkenshaw and Gomersal—more especially at the former place—have been dissatisfied with the charges made by the Gomersal Gas Company, and now it is probable that they will agitate for a considerable reduction. Seven or eight years ago a similar agitation took place; the price then charged by the Company being 5s. 5d. per 1000 cubic feet. Many of the consumers in both places cut off the supply, and for one or two seasons the Birkenshaw Local Board declined to light the public lamps. The agitation was successful; the price being reduced to 4s. 2d. per 1000 cubic feet, with 5d. discount to ordinary consumers and an extra 3d. to the large consumers, while to the public lamps the price was fixed at 3s. 6d. net. This being as great a reduction as could be obtained at the time, most of the ratepayers again commenced using the gas; but a considerable number who then cut off their supply never resumed it. The Gomersal Company's Act fixes its area of supply as Gomersal, Birkenshaw, and Hunsworth, with the exception of the hamlet of East Bierley and Toftshaw, which are included in the area of the Drighlington and Gildersome Gas Company. As there are no boundaries of the hamlet of East Bierley defined, it has always been a disputed point between the two Companies as to where the rights of the one end and the rights of the other begin. When the Drighlington Company attempted a short time ago to get an Act to prevent Mr. Matthew Hillas from supplying gas in their district at Dudley Hill, they also sought to obtain a definition on this point; but as Gomersal had established themselves in part of the disputed district, to which they were supplying largely, the latter offered opposition to the Bill, which, as is generally known, was thrown out. To compete with Mr. Hillas, therefore, the Drighlington Company reduced their price to 2s. 6d. per 1000 cubic feet, with the same discounts as before. They state that in consequence of this they cannot make the gas so profitably as they previously did with a much greater consumption. Looking for opportunities for increasing the sale of their gas, one of their officers intimated to the collector of the Birkenshaw Board that the Company would supply the public lamps in the Birkenshaw district at 2s. 6d. per 1000 cubic feet. This offer was reported to the Gas Committee, who instructed the collector to make further inquiries. That officer accordingly went to Drighlington; and there the offer was again verbally given, provided that the Board would take the gas for not less than seven years. It was then stated that the Company had received notice to supply Messrs. Oddy, of the Moorside Mills—a firm in the disputed district—which Gomersal had previously supplied; but this having come to the knowledge of the Gomersal Company, they took such measures as will lead to a continuance of their supply there. A few days later the Gomersal Company issued notices as to increased discounts, under which the household consumer will pay 3s. 6d. per 1000 net, against 3s. 9d. previously; while much greater discounts were offered to the large consumers—the net price to these graduating from 3s. down to 2s. 3d. This notice, however, was not satis-

factory to many of the Birkenshaw consumers; and various preliminaries were agreed upon with regard to getting up an agitation for the benefit of the household consumers, who, it was considered, had been practically ignored in the reduction, while in the case of the large consumers the reductions were tangible. A town's meeting was on the point of being called; but it was decided to delay the matter until the Board had considered the offer of the Drighlington Company. This the Board did; and it was decided to send a deputation to each Company. There the matter rests at present, as no steps will be taken until the result of the efforts of the Board is made known. The feeling on the matter is so strong in Birkenshaw that nothing but a substantial reduction will be accepted; the opinions of the Local Board are quite as strong. Unless such a reduction is made, they will either refuse to light the lamps or take the Drighlington gas, as it is within their power to do. The Drighlington Company state that it would not pay them to take the public lamps alone in Birkenshaw; but they think that if the Gomersal Company do not reduce the price, some person in Birkenshaw will take a similar course to that pursued by Mr. Hillas at Dudley Hill. They say that they would have no option, as the Bradford Corporation pleaded, but to supply to such person as much gas as he wished if he only placed a meter in their district. They would not consent, however, to the Birkenshaw people only using them to "force the hand" of Gomersal, and then dropping them, but state that if they are called upon to supply Birkenshaw, they must have an agreement for seven years, or some such term. Should Birkenshaw decide to take this course, there are two points where the Drighlington mains approach the boundary of the district—viz., at the station and at the Mirfield Institute, Westgate Hill; and the mains to Westgate Hill will be greatly enlarged so as to send the supply into Birkenshaw by way of the Bradford Road. In Gomersal the feeling of the people is not so openly developed as at Birkenshaw, partly because they have no chance of getting a cheaper supply, even indirectly, as at Birkenshaw, and partly because of interest in the Gas Company. But should an agitation be commenced at Birkenshaw, there are many who took part in the previous agitation who will be ready to join with Birkenshaw again. A proposal to light the streets of Gomersal is in abeyance, because the few members of the Board who are not interested in the Gas Company will not consent to pay 3s. 6d. per 1000 cubic feet—the price stipulated by the Company on being approached on the subject at the end of 1887 and again a month ago. The Company consider they are most unjustly abused for what the people consider the "high charges," because there are several things which prevent them from making gas as cheaply as other companies. They possess a very extended area, which they are compelled to supply; but considering how large their district is, the consumption is exceedingly limited. For a number of years the full dividends allowed by their Act have not been paid; and what is required before they can profitably reduce the prices of the gas is a greatly increased consumption. They have collated a list of the charges made by other companies in Yorkshire; and with this as a basis, they state that very few are lower in price than themselves, when the amount of consumption and attendant expense are taken into consideration. The action taken by the Drighlington Company is regarded as one prompted by revenge for the part taken by Gomersal in opposing their recent Bill; and as the failure of Drighlington gave the death-blow to the notion that a gas company had a right to the monopoly of the supply in any prescribed district, the feeling seems to be general among the shareholders of the Gomersal Company that if Drighlington is determined to fight them, they will have no option but to fight also, and reduce their prices, even if by doing so they preclude the possibility of as good dividends as before. The position of affairs between the two Companies is very peculiar; and the Birkenshaw people are fully alive to the advisability of taking advantage of the state of things.

WILTON CORPORATION GAS SUPPLY.

REPAIRS AND EXTENSIONS AT THE GAS-WORKS.

At the last Meeting of the Wilton Town Council—the Mayor (Alderman W. V. Moore) presiding—the subject of the condition of the gas-works of the Corporation was under consideration.

The Town Clerk (Mr. King) stated that at the previous meeting of the Council, it was decided that the consideration of the repairs to the gas-works should be left to a Committee, and that they should report. The Committee met on the 11th of June, and, by request, Mr. Norton H. Humphrys, Assoc. M. Inst. C.E., gas engineer, of Salisbury, was present, and joined them in an inspection of the works. He had submitted a report to the Committee as a result of his examination of the present condition of the undertaking, and the probable cost of carrying out the necessary repairs to put the works in a thoroughly efficient state; and this report was now placed before the Council. In it Mr. Humphrys stated that the whole of the apparatus, with the exception of the holder, was in a very dilapidated state and completely worn out. Having enumerated the kind of works necessary to be carried out, Mr. Humphrys remarked that, the Corporation having acquired an undertaking the plant of which was to a great extent useless and worn out, the future prosperity and stability would be greatly promoted by their action at the present crisis. Boldness and energy would place them in a sound position; but any attempt in the way of patching would only result in annoyance, trouble, and loss. A permanent addition to their existing large capital would be a perpetual hindrance to progress; therefore he strongly recommended that the balance required to make up, with the moneys they had in hand, the sum needed to carry out the work, should be raised by a temporary loan. It would be readily taken up at low interest, and the new plant would admit of such economy in working expenses that it could be easily liquidated, and in a few years' time leave their undertaking in a sound condition, and themselves in a position to supply good gas at about 4s. 2d. per 1000 cubic feet. The work, he urged, should be proceeded with at once, as a great part of it ought to be completed before Michaelmas.

Mr. CARSE said the Council all knew that something would have to be done soon. When the Corporation took over the gas-works they knew they would have to spend about £1500 upon them. He thought the only thing they could do then was to adopt the report, so that Mr. Humphrys could proceed to prepare plans; after which the Council could ask Messrs. E. Cockey and Sons, Limited, of Frome, to tender for carrying out the work. It was necessary that something should be done quickly, or they would be without gas in the coming winter. He moved a resolution in accordance with his suggestion.

Mr. HOLDSWORTH, in seconding the proposition, said he thought the report ought to be adopted, and that Mr. Humphrys should be requested to get out plans as soon as possible. This would not bind the Council in any way to the expenditure of a large sum forthwith; but would enable them to ascertain all they desired to know before doing so.

Mr. YATES moved an amendment that the report be further considered at a special meeting of the Council to be at once convened.

Mr. THRESHER seconded this proposition.

After some conversation, the matter was put to the vote, when the amendment received the support of the mover and seconder only. The original proposition was then carried.

BLACKPOOL CORPORATION GAS SUPPLY.

NEW CONDENSING PLANT.

The new condenser which has been erected at the Blackpool Corporation Gas-Works by Messrs. R. Dempster and Sons, of Elland, from the designs and under the supervision of the Corporation Gas Engineer (Mr. John Chew) was recently started by the Chairman of the Gas Committee (Alderman Hall), in the presence of a full gathering of the Committee—Mr. J. Chew and Mr. W. Chew (the Assistant Manager) being in attendance. The condenser is of the annular type, and consists of two rows of pipes, 20 feet high and 3 feet in diameter, placed ten in each row. They stand on an open stone plinth, having cast-iron moulded bases; the tops being finished with a cast-iron cornice, and surmounted with ornamental balustrade, which, while giving a finished appearance, serves as a guard in high winds. After the condenser had been started, the company adjourned to the Committee-room, where refreshments were served. In the course of a few remarks made by the Chairman on the occasion, he gave a retrospect of the progress of the gas undertaking from the time when the gas was 7s. 6d. per 1000 cubic feet and rates to the extent of 6d. and 7d. in the pound were levied towards making good the deficiency on the works. Reverting to the time since the erection of the old condensers in 1875, when the price was 5s. per 1000 feet, to the present, when it is 2s. 6d. per 1000 feet, he said that during this period of 13 years the amount of profit earned towards the relief of the rates in Blackpool was £43,500—a sum which, had it been employed otherwise, would nearly have extinguished the cost of the gas-works. The question whether some steps should not be taken in future to more quickly pay off the debt instead of extending it, he thought was well worthy their consideration (a sentiment which was re-echoed all round the room). The progress of the works had been remarkable. In 1875 the annual output was 30 million cubic feet; while last year it was 120 millions. The preparation of buildings and appliances for making and distributing this rapidly increasing bulk of gas for consumption was a great strain upon their officials, who he was glad to say had been able to meet it, at the same time keeping the capital account per 1000 cubic feet of gas made as low as any in the country. Speeches by the other members followed, and the proceedings terminated.

THE FLEETWOOD IMPROVEMENT COMMISSIONERS
AND THE GAS-WORKS.

At the last Meeting of the Fleetwood Improvement Commissioners, the Chairman (Mr. T. Seed), in accordance with previous notice, moved—"That the Commissioners consider the purchase of the gas-works." He said he had consulted several members of the Board on this matter, and some of the most influential men in the town, and they approved of it. He thought the time had arrived for the Commissioners to enter into negotiations with the Gas Company. He was on the Committee which last approached the Directors to ask for a reduction in the price of gas; and though they said that nothing would give them greater pleasure than to lower the price, no concession had yet been made. He did not wish to say anything to disturb the good relations existing between the Company and the Commissioners; but he thought the Directors should be waited upon with the object of transferring the gas-works to the local authority. It was essential that the town—in fact all towns—should own both gas and water works; and he would like the Commissioners to agree on this business, and appoint a Committee to enter into negotiations, but not to conclude a bargain. If the works could be secured at a reasonable price, he would advise the town to buy. He moved that a Committee be appointed to deal with the subject. Mr. Loft-house seconded the motion. He said he thought that if the works could be bought at a reasonable price, the town ought to have them. If the Company would not sell the works, let them reduce the price of gas. The consumers ought not to be paying more than 3s. 6d. per 1000 cubic feet for gas in Fleetwood; and it would pay the Company at that price. If they would not meet the Board in a reasonable manner, he would suggest that a company should be formed, and that they burn paraffin oil for twelve months. The Chairman said he had had offers from two electric lighting companies to furnish the town with the electric light. He thought, however, that the purchase question should be fully discussed before they considered electricity. Mr. Foster, in answer to a member, said the Board did not make the Company any definite offer before, but £25,000 was mentioned. The Company intimated that they could not think of accepting anything less than £35,000. Mr. Marginson thought they should approach the Company in a friendly manner, and point out the advantages that would accrue to the inhabitants of the town by the purchase. The Chairman believed the Board would be supported by the ratepayers. If the Company would not negotiate with them in a reasonable manner, it would be necessary to call a meeting of ratepayers on the subject. A Committee was then appointed to wait upon the Directors of the Company.

HUELVA GAS COMPANY, LIMITED.

The Directors of the Huelva Gas Company, Limited, the stock of which is chiefly owned in Glasgow, have issued the balance-sheet and statement of accounts for the year ended March 31 last. In the course of their report they state that they are gratified to find a continuance of the steady progress which has hitherto characterized the history of the Company. The number of meters on hire, the lights employed, and the consumption of gas have all increased, yielding results which have correspondingly augmented the revenue of the Company. Coke was in steady demand during the year, and a ready sale was found for a large proportion of the production. The demand is being encouraged, and seems likely to increase. Tar was not so freely sold as formerly, owing to the competition from other towns (even from Gibraltar, where the Gas Company are glad to get rid of it), and was offered at much lower prices than were being secured by the Huelva Company. To meet this, the Directors authorized the reduction of the price to a point that would meet any competition, and this had the desired effect. Regarding the condition of the works, &c., the Directors remark that the whole of the plant, pipes, services, &c., have been maintained in good order, and that all renewals have been effected from revenue. The property account stands at £22,120; being £3565 more than at March 31, 1887. This addition is accounted for by the payments to date for the new gasholder, smithy, and meter-shop mentioned in the report for the previous year, and for the usual extensions consequent on an increasing business. The contract for the new holder was entrusted to Messrs. Laidlaw, Sons, and Caine, Limited, of Glasgow, who have carried out the work under the superintendence of Mr. W. R. Copland, C.E., also of Glasgow, and Mr. Adam, the Manager of the Company in Huelva. The holder is now completed and at work; and will benefit the operations of the Company, which hitherto have been hampered by the limited storage accommodation. The profit and loss account shows a balance of £2589. Bearing in mind that the capital upon which dividend will fall to be paid in the ensuing year will be £25,000, the Directors have considered it more prudent to recommend the distribution of 6½ per cent. only, being the same as last year, to be paid one-half on Aug. 28, 1888, and the other half on Feb. 28, 1889, free of income-tax, which will absorb £1364; that £350 be added to the reserve fund, bringing it up to £2500; that £200 be written

off meters; and that the balance of £675 be carried forward. The Directors consider that by the writing off against meters in the floating stocks account, they will have dealt with this account in such form as will leave it subject only to very moderate writings off in future. It may be remarked that the Company have now been in existence about eight years. The dividend began at 3 per cent.; then it was 5 per cent. for two years, 6 per cent. for one year, and 6½ per cent. for three years.

HAWICK GAS COMPANY.

The annual report of the Directors of the Hawick Gas Company, together with the statement of accounts and balance-sheet for the year ending the 26th ult., which will be submitted at the meeting of shareholders next Friday, has been issued. In their report the Directors express much regret in having to inform the shareholders that, in consequence of continued ill-health, Mr. John Melrose, who had been Chairman of the Board for the long period of 25 years, had felt himself compelled in the course of the past year to resign the duties of the chairmanship. In place of Mr. Melrose they had appointed as their Chairman Mr. Thomas Laidlaw, one of the oldest Directors. They bear testimony to the zealous and efficient manner in which Mr. Melrose performed his duties. The Directors have recently entered into a very favourable contract for the sale of the residual products at a greatly enhanced figure; and, having in view the increase to be derived for such products during the next few years, and also the large unapplied balance in hand, the Directors feel justified in recommending that the price of gas for the ensuing year be reduced to 3s. 1½d. per 1000 cubic feet, being a reduction of 2½d. per 1000 cubic feet. It may be mentioned, in connection with this matter, that the shareholders receive a fixed dividend of 10 per cent.; and that, according to arrangement with the consumers, the balance, after meeting expenses, goes to reducing the price of gas. Last year a similar reduction was made. The fact of the Company being in a position to recommend such a reduction at the forthcoming annual meeting testifies to the excellent management of the Directors, and to the value of the services of Mr. J. Smith, their Manager. During the past year 4405 tons of coal and shale were purchased, at a cost of £3205 18s. 3d. The payments for lime, wages and salaries, taxes, discounts, interest, &c. amounted to £2070 6s. 2d. The cooking-stoves and meters purchased during the year for re-sale involved an outlay of £96 15s. 1d. On meters and cooking stoves to be hired out, and pipes, &c., there was an expenditure of £205 9s. 6d. As dividends for the year ending Whitsunday, 1887, and for the previous year, the sum of £1583 10s. was paid. Then the paid-up deposits, the loans on promissory notes, and the payment into the bank on deposit receipt, amounted to £800. The total disbursements were £7961 19s. The amount received for gas for the year ending Feb. 1, 1888, with a small amount for arrears, was £6608 3s.; the total receipts during the year were £7961 19s. The share capital of the Company at last year's balance was £15,750. The premium realized on the issue of new stock and the amount of the reserve fund brings this up to £23,375 15s. 6d. The amount borrowed on promissory notes stands at £2524; the deposits received from consumers up to May 26, 1888, stand at £266 15s. On May 26, 1887, the balance was £4486 18s. 4d., out of which the dividend was paid, amounting to £1575; so that carried to this year's account there is a balance of £2911 18s. 4d., to which is added £1194 6s., as profit on the year's trade—making £4106 4s. 5d. The grand total of the liabilities, therefore, is £30,272 14s. 11d. The chief asset is the works and plant, standing now at £26,039 13s. The quantity of gas sold during the year, at 3s. 4d. per 1000 cubic feet, was 39,100,700 cubic feet.

DUNDEE WATER SUPPLY.

A Special Meeting of the Dundee Water Commission was recently held to receive the accounts for the past financial year.

Mr. CRAIG (the Convener of the Finance Committee) moved that the accounts be remitted to the Finance and Works Committee, to bring up estimates for the ensuing year. In doing so, he said it was his honour and privilege to announce that the Commission had the handsome surplus of £1758. He explained how this had been brought about. The estimated assessable rental of the town had increased, which was satisfactory in more ways than one—indicating, as it did, the occupation of more houses, and perhaps also the use of more property for trading purposes. The amount estimated last year from the domestic rate was £18,125; and the actual sum obtained had been £18,243—a surplus of £118. The public rate had yielded more. It was estimated that the income would be £2833 6s. 8d., and it had turned out to be £2884 19s. 4d. But the great increase had arisen on the special rates. These were estimated to produce £20,600; whereas they had actually yielded £22,615. They expected to get from the Police Commission £500 more than they had allowed for public purposes; but notwithstanding the loss of this money, they were in the happy position of having the large surplus already mentioned. The total income was estimated at £41,158 6s. 8d., while the sum actually received amounted to £42,851 11s. 4d. The surplus anticipated was only £28 6s. 8d.; but, as he had already said, it amounted to £1758. This large increase was mostly due to the revenue from special rates, and chiefly from meters. It might partly be attributed to the dry season last year; and so might be looked upon as temporary, and not to be depended upon for the current year. Up to May, 1887, the Commissioners had expended £390,910. During the year ending in May last they spent on the second Lintrathen main £16,081; for town extensions, £1328; for the new Tay Bridge main, £2194; and other matters, £133—making a total expenditure on capital account for the year of £19,737. Adding these figures to the amount previously spent, the total was £411,648. Then there was a balance of £18,446—consisting of the amount due to the revenue account, stores in hand, and cash in Royal Bank; thus making the total capital account £802,919. Turning to the revenue account, the domestic rate yielded £18,243; the public rate, £2888; and the special rate, £22,615. The total revenue, deducting £900 as irrecoverable, was £42,851; while the total expenditure was £41,093—leaving a surplus of £1758. The estimated expenditure was £41,130; while the actual expenditure had been £41,093—being £36 under the estimate. Although they had the surplus he had mentioned, the members need not imagine that there would be a reduction of the domestic rate. There would be a heavy amount of extra interest to meet this year, on account of the construction of the second pipe to Lintrathen. He calculated that £1800 to £2000 more would be needed for payment of interest; and in this case the whole of the surplus would be required. In laying so satisfactory a statement before the Commission, the Committee could not do less than express their thanks for the deep interest taken in the works by their officials, Mr. J. Watson, M. Inst. C.E., and Mr. Smith. They had been very assiduous in their respective departments; and he believed it would be impossible to get a better staff of officials.

Mr. ROBERTSON seconded the motion.

The CHAIRMAN (Baillie Tulloch, who was for several years Convener of the Finance Committee) also bore testimony to the admirable way in which Mr. Watson and Mr. Smith performed their duties.

It was agreed that the statement of accounts should be printed and circulated; and it was remitted to the Finance and Works Committees to bring up estimates at the annual meeting to be held this month.

NOTES FROM SCOTLAND.
(FROM OUR EDINBURGH CORRESPONDENT.)

EDINBURGH, Saturday.

I feel inclined to be jubilant to-day over the announcement of an agreement between the Edinburgh and Leith Gas Company and the Edinburgh and Leith Corporations, because the terms agreed upon have fully borne out what I have all along contended for—viz., that the Joint Committee had not sufficiently studied the question or properly approached it; and that they had not offered value for the undertaking which they wished to acquire. All this is past now. The Corporations have adopted the position which was offered them by the Company in December last—the examination of their works by Mr. George Livesey; and they have advanced their offer a good deal beyond the 8 per cent. which they started with as the basis of their offer. Negotiations were carried on almost without intermission, but with great secrecy, during the whole week. In the preceding week, it had transpired, the parties agreed on the terms on which the transfer was to be effected, provided a favourable report on the Company's financial position was obtained from Mr. Lass, and on the condition of its works and plant from Mr. Livesey. The Company had no reason to fear that even a hostile examiner would report unfavourably; and they must have felt that, with the two gentlemen named, they were perfectly safe. A joint report by Mr. Lass and Mr. Livesey was submitted on Thursday night; and, being favourable, the provisional agreement of June 21 was, on the succeeding day, adopted by the parties. There was need for expedition in carrying through the agreement, because the Corporations' Bill must soon be up for hearing before the House of Commons Committee to which it has been referred. It would appear that the negotiations proceeded much more amicably than the public were led by the Joint Committee to expect they would be. Readers of my "Notes" must know that I have constantly endeavoured to counteract utterances, official and otherwise, of the Joint Committee which were calculated to throw odium upon the Company for the attitude they had taken up. The doctrine I have held by was that, in approaching a matter of this important kind, every description of bias should be laid aside; and the only question which should be considered was what the concern was absolutely worth. Unfortunately, the Joint Committee seemed to think they were engaged with an enemy; and instead of taking the sensible course of disarming criticism by themselves acting altogether fairly and above-board, they took to damaging the reputation of the Company in the eyes of the public, hoping, I suppose, to create a hostile public opinion before which the Company would have had to succumb. Fortunately, however, the tactics of the Committee did not succeed. I expect the supporters of the Committee will now come forward with the information that their superior handling of the question has brought about the settlement; and that the terms which they have secured are much lower than the "grasping" and "unreasonable" Company were prepared to accept. Indeed, we have not to wait for an instalment of this policy. On Thursday the *Scotsman*, which has all through this matter blindly followed the Joint Committee, told its readers, in a leading article, that the Company had most wisely departed from their recent stand-off attitude, and had entered into negotiations with the Corporations. It would have been correct to have said that the Joint Committee, seeing the futility of the policy they were pursuing, and fearing to incur further needless expense, had agreed to a proposal which the Company made months ago—that the agreement should be based upon a report by Mr. Livesey. The only variation upon that proposal is that Mr. Lass is associated with Mr. Livesey in the examination, and that the basis of agreement is now made before, and not after the examination. The Company have succeeded upon the matter of terms; and on the question of policy they have undoubtedly also had the best of it, because they have vindicated their position of last December, both by the augmented offer which was made to them in London, and by the adoption now of their proposal for an examination of their works and books. On the side of the Company the affair has been well conducted. There has been no panic; but a careful survey of the question, and a firm determination to secure an adequate price—the Directors knowing that their undertaking was worth more than had been tendered to them. On the other side, I am compelled to say that if the Joint Committee acted all through in the public interest, they did not show much capacity for dealing with the subject. I fancy they were troubled over the fact that the Leith Company at one time appeared to be willing to accept much less than they will now get; but the Committee ought to have remembered that this was before the agreement with the Edinburgh Company. As soon as this agreement was effected, it became the standard by which to fix the price for the Leith Company. The Committee all through ignored this; and they somehow seemed to regard the Edinburgh price as an exceptional one, suited to the exceptional position of that Company. There was a considerable amount of justification for their taking this view; but where they failed, if they really wished to settle the question (which I very much doubt), was in their refusal to accept explanation at the hands of the Leith Company, or to satisfy themselves as to the position of the Company. The hostility of their attitude, and the way in which they have at last fallen in with the proposals of the Company, force me to the conclusion that up till now the Committee did not really desire to have the matter settled.

The agreement between the Joint Committee and the Leith Company, as might have been expected, has largely affected the stock of the latter. Starting on Monday at £62 10s. per £25 share, it rose on Tuesday to £64; on Wednesday to £66; on Friday to £70; and to-day is quoted at £71. The stock of the Edinburgh Company began the week at £77; rose on Wednesday to £77 10s.; and on Friday to £78, at which it now stands.

Perhaps the only other notable incident of the week in connection with the Edinburgh and Leith Gas-Works transfer is the collapse of the ratepayers' opposition in Parliament to the Corporations' Bill. When the Bill was before the Referees in the House of Commons on Wednesday, no one appeared for the 86 ratepayers who had petitioned against the measure; and they were accordingly deprived of *locus standi*. This is a very practical comment on the argument which has been sometimes used, that the opposition of the ratepayers had been the cause of much expenditure in connection with the negotiations; it never was worth the slightest serious consideration.

The Dunfermline Gas Company held their annual meeting on Wednesday. The report stated that an increased sale of gas, equal to 4 per cent., had been experienced, and highly satisfactory returns from the carbonizing and purifying departments were being obtained. The Directors recommended that a dividend at the rate of 9½ per cent. per annum should be declared upon the issued stock of the Company, and a reduction of 2d. per 1000 cubic feet made in the price of the gas for the current year. The revenue from the sale of gas had been £8290. It was also reported that the total assets of the Company amounted to £28,552 11s. 8d., as compared with £28,423 10s. 5d. last year; and the total revenue to £8931—a considerable increase on last year. The dividend for the previous year was at the rate of 9 per cent.; the payment on the present occasion being the highest which has been made.

The Forres Gas Company, at their annual meeting on Monday, declared a dividend at the rate of 7½ per cent. per annum; and decided to reduce

the price of gas from 7s. 1d. to 6s. 8d. per 1000 cubic feet. The Company gives a discount of 10d. per 1000 feet for prompt payment.

Twenty shares of the Stirling Gas Company were recently sold for £7 9s. each.

The accounts of the Edinburgh and District Water Trust for the year ending May 15 last, which have been made up, show that the ordinary revenue from water-rates was £81,666 14s. 4d., and that the receipts from other sources come to £2573 7s. 10d.—in all, £84,240 2s. 2d., or an increase of £2001 11s. The property account shows a balance of £1,137,708 1s. 1½d.; and the sinking fund a balance of £2839 4s. 9d. The total expenditure for the year, including annuities to holders of debentures, amounted to £81,864 16s. 3d., as compared with £77,707 6s. 3d. in the preceding year—being an increase of £4157 10s. The apparently large rise in the outlays is due to increased renewals and repairs of pipes. For example, the repairs up to the end of the financial year in 1887 was £2616 4s. 6d.; whereas during last year these cost £4194 18s. For renewals in 1887, £1322 1s. 11d. was spent, as against £4217 1s. last year. Otherwise, under such heads as salaries, wages, taxes, &c., there has been a decrease in the expenditure. The balance-sheet shows a sum of about £14,000 at the credit of the bank account; and in the account of charge and discharge there appears an accumulated cash balance of £6274 8s. 7½d. Up to the end of the financial year, about £8000 had been expended in connection with the new filter at Alnwickhill.

(FROM OUR GLASGOW CORRESPONDENT.)

GLASGOW, Saturday.

At the annual meeting of the Stewarton Gaslight Company, a satisfactory report was submitted by the Directors; and a dividend of 12s. 6d. per share was declared. On Monday evening of this week, a special meeting of the Company was held, at which it was unanimously agreed to erect a new bench of retorts, at a probable expense of £200. When the contemplated alterations and repairs have been completed, the Directors anticipate that they will be able to carry on the works with greater economy, and thereby earn higher profits.

The annual meeting of the Kilmalcolm Gas Company was held on Thursday, when it was agreed to declare a dividend of 6 per cent. It was also resolved to reduce the price of gas to consumers by 5d. per 1000 cubic feet; the price for the ensuing year being 5s. 10d.

At the annual meeting of the Kelso Gas Company, held on Wednesday, it was resolved that the price of gas to ordinary consumers be reduced 5d. per 1000 cubic feet—from 4s. 7d. to 4s. 2d. It may be mentioned that since the year 1881 the price of gas at Kelso has been reduced to the extent of 1s. 3d. per 1000 feet. It was also unanimously agreed that the contract price to the Police Commissioners for supplying the public lamps should be reduced from 23s. 6d. to 22s. per lamp. The usual dividend of 10 per cent. was declared.

At the annual meeting of the Jedburgh Gas Company on Wednesday, it was desired to declare a dividend of 7½ per cent. From the accounts for the past year, it appears that £1668 9s. was received for gas, as against £1677 11s. 7d. in the previous year.

I understand that the price of gas in Galashiels, for the year 1888-9 will be 2s. 11d. per 1000 cubic feet; being a reduction of 3d.

It is worthy of mention that, in connection with the new sewage-works in process of construction for the burgh of Kirkintilloch, an "Otto" gas-engine of 8-horse power nominal is to be erected for driving the pumping machinery. This will involve the laying down of a 3-inch pipe from the gas-works to the sewage-works to supply the engine.

Glasgow Corporation 9 per cent. gas annuities changed hands this week on the Glasgow Stock Exchange at £280 per share.

The Jedburgh Police Commissioners have resolved to apply to the Public Works Loan Commissioners for a loan of £2300 in connection with the additional supply of water that is about to be brought into the town. The works have been commenced, and are now being pushed forward.

A steady tone has ruled in the Glasgow pig-iron market this week; and values have been well maintained at, and slightly above 38s. per ton cash for Scotch warrants. The quantity of pig iron in store is practically a million tons; and it remains to be seen how much more the market can carry without breaking down. Still there does not seem to be any prospect of the deliveries into the warrant stores undergoing any check. There have been a number of transactions in hematite warrants this week; the top price reached being 42s. 2d. per ton cash. Cleveland warrants have not been much in demand. Some more activity is likely to show itself alike in the local foundries and in the malleable iron and steel works.

The coal trade has been somewhat active during the past week; and prices are decidedly hardening in tone. Steam coal is going away freely; and most of the collieries are now working full time. The prices generally rule from 7s. 3d. to 7s. 9d. per ton f.o.b. at Clyde ports. Splint coal for gas-making purposes is selling at easier rates; and it is publicly stated that in first-class qualities of cannel coal, contracts have been concluded at a reduction of as much as 4s. per ton in some cases.

NANTWICH WATER SUPPLY.—The Nantwich Local Board have finally decided to adopt the smaller of the two schemes which have been under consideration for a long time, for providing an extra reservoir at Baddiley. The new works will be equal to the storage of 22 million gallons. The land required (15 acres), is owned by Mr. G. E. Wicksted; and as he refuses to put a price upon it, the Board will have to take action to acquire it compulsorily. Meanwhile, the work of laying new service-pipes in the town is being proceeded with, and the river has been temporarily diverted to allow the workmen to lay a main across the bed.

THE SMOKE ABATEMENT MOVEMENT IN THE MANCHESTER DISTRICT.—At a recent meeting of the Committee of the Manchester and Salford Noxious Vapours Abatement Association, the question of popularizing the use of gas-stoves, cookers, &c., as a means of diminishing the smoke nuisance, was again under consideration; and it was resolved to once more approach the Gas Committee of the Manchester Corporation on the subject. It was determined to take steps for making known the extent of the action taken by the Nuisance Committee against offenders under the smoke bye-laws, and the penalties imposed by the Magistrates. The Secretary was authorized to arrange for excursions by firemen and others to see certain systems of smokeless firing of steam-boilers; and it was determined to publish a tract on smoke prevention, explaining various efficient methods. In connection with these proceedings, Mr. T. Fletcher, of Warrington, wrote to a local paper to call attention to the fact that his works, where about 200 hands are employed, are carried on absolutely without smoke, and have been so since their first erection. He added: "Our smokeless chimneys include steam-boiler, smithy fires, and japanning-stove. Further than this, my own house is, and has been for many years, practically smokeless, the whole work (including fires, baths, laundry work, cooking, and conservatory heating) being carried on without other smoke, dust, or dirt. The absence of smoke has not been studied—it is simply an incidental result of a system which we carry out, because it is convenient, and is economical in labour and in cost."

CURRENT SALES OF GAS PRODUCTS.

LIVERPOOL, June 30, 1888.

Sulphate of Ammonia.—The market has been very quiet; but, notwithstanding the general remark that business is at a standstill, all parcels which have been placed on the market have readily found buyers. It may therefore be assumed that any weakness apparent is but on the surface; and the insignificant decline, in spite of all attempts to bring about a rapid fall, is assuredly an indication of the underlying strength of the position. It is, in fact, clear that any existing weakness has been created entirely by reports from this side, which have been wilfully perverted, and are simply intended to keep foreign consumers off the market. Consequently, as the dealers were the only buyers, such producers as wished to sell their make before the end of the half year, had to accept the lower prices offered; and thus in some instances £11 10s. has been accepted. A fair portion of the near production being already sold, while the repairs usually undertaken at many works in July will still further curtail the available parcels, it seems most unlikely that prices will suffer further in July. Unless symptoms are very deceptive, an upward movement would be more probable.

P.S.—Special attention has been called in a French agricultural journal to the small shipments from Hull during the week ending June 16—viz., 20 tons. Such reports being apt to be very misleading, it seems a pity that it was not at the same time pointed out that the sulphate which used to be shipped from or *via* Hull, is now being largely diverted to other ports; and a few simple facts discountenance the idea, which the above statement conveyed, that the export demand has ceased. Some 700 tons arrived in Hamburg during the corresponding week; and the total shipments during the first fortnight in June exceed those of the corresponding period in 1887.

LONDON, June 30.

Tar Products.—The higher products are uniformly weak and unsaleable. There is little demand for naphthalene, but at prices which scarcely pay distillers to extract. Carbolic acid is in better request, but is still dull for the time of the year. The price of anthracene is maintained; but very little business is doing in this article—the make of all the tar products being for the moment at a minimum. Prices: Tar, 15s. to 20s. per ton, according to position. Benzol, 90 per cent., 2s. 5d. per gallon; 50 per cent., 2s. per gallon. Toluol, 1s. 4d. per gallon. Solvent naphtha, 1s. 1½d. per gallon. Crude naphtha, 30 per cent., 11d. per gallon. Light oil, 3½d. per gallon. Creosote, 1½d. per gallon. Pitch, 12s. to 15s. per ton. Carbolic acid (crude), 3s. 5d. per gallon. Cresylic acid, 10d. per gallon. Tar salts, 15s. per ton. Anthracene, 30 per cent., “A” quality, 1s. 4d. per unit; “B” quality, 1s.

Ammonia Products.—The manure season having closed, shipments of sulphate have been small; and what buying there is is chiefly of a speculative character. A good deal of comment is being made on the mode of selling sulphate. An effort to sell on a percentage instead of a given strength is being attempted; and again the different conditions of selling that obtain in London and in the country respectively have long been a standing anomaly. This would be avoided if sales were made on percentage of ammonia. Prices are as follows:—Sulphate of ammonia, £11 10s. to £11 15s. per ton, less discount. Gas liquor (5° Twaddell), 8s. per ton, with a rise or fall of 1s. 6d. per degree. Liquor ammonia, 2d. per lb. Carbonate of ammonia, 3½d. per lb. Muriate of ammonia, brown, £18 per ton; white, £23. Sal ammoniac, £30 per ton.

[From the *Chemical Trade Journal*, June 30.]

Sulphate of Ammonia.—The absence of orders in this market makes it difficult to fix the value. In fact, there are no buyers at the present moment; and every parcel that is offered tends to bring down the price to a level that will make speculation profitable. A fair quantity is being shipped, however; but this is not the result of any very recent business. Beekton price is £11 15s.; but we hear that some quantity has been sold on Beekton terms at £11 7s. 6d. At Hull business has been done at £11 12s. 6d. to £11 11s. 3d.; while Liverpool and Leith quotations stand at £11 10s. Buyers are holding off, in the expectation of seeing lower prices; but stocks are still low, and there is no inordinate quantity pressing on the market.

Tar Products.—Slackness and absence of demand for benzol continues to reign supreme in this market, with the result that 50/90's has fallen to 2s. 3d. d/d London, which is equal to 2s. 1½d. f.o.b. Goole or Hull. Solvent naphtha is a trifle weaker, though there is a fair demand for this article. A rumour is current that the Government has bought up the picric explosive patents; and, on this account, some makers are holding to carbolic acid rather than offering it for forward. For July-December, 3s. 4d. has been offered for 60's; but we believe not accepted. Anthracene remains *in statu quo*; there being no buyers at present. Pitch remains, as stated in our last prices current, at 13s. Garston; and it is very doubtful whether the higher prices said to have been obtained recently were *bona fide*.

It is reported that a Company has been formed, with a nominal capital of 12 million dollars, for the purpose of introducing natural gas into Chicago.

The Brynbo Water Company, at a meeting held last Friday week, decided to raise further capital to the extent of £10,000, in ordinary shares of £10 each.

The last of the vacation visits of the students of the Institution of Civil Engineers for the present session took place last Thursday, when the party left Liverpool Street Station at 1.35 p.m. for the East London Water-Works at Lea Bridge.

The Automatic Electrical Corporation, Limited, has recently been registered, with a capital of £75,000, in £20 shares, with the object of supplying electricity for lighting and other purposes within the United Kingdom and elsewhere.

The Godalming Gas Company, having decided to manufacture sulphate of ammonia, have placed an order for the necessary plant with Messrs. R. and J. Dempster, of Manchester; and the work will be carried out under the direction of Mr. S. Bark, the Company's Engineer.

The Engineer of the Llanelly Gas Company (Mr. A. G. Browning), having considered the various systems of regenerative firing, has decided on adopting that of Messrs. R. and J. Dempster, of Manchester, who will at once proceed with the erection of four complete benches.

We are informed that the sulphate of ammonia plant ordered from Mr. Henry Simon, of Manchester, by the London and North-Western Railway Company for their works at Crewe (to which reference has been made in the JOURNAL) has now been successfully started. We also learn that Mr. Simon has been favoured with an order by Messrs. Mitsui and Co., of London, to supply them with one of his 10-ton plants for the continuous manufacture of sulphate of ammonia. It is to contain all Mr. Simon's most recent improvements, and is for erection at Yokohama.

REDUCTIONS IN PRICE.—The Directors of the *Burnham Gas Company* have given notice that, on and after the 24th ult., the price of gas will be reduced from 5s. to 4s. 7d. per 1000 cubic feet.—Messrs. Wilson Bros., of Cornholme, have entered into an arrangement with the Directors of the Todmorden Gas Company, whereby the Burnley Valley district will be supplied with gas by the Cornholme Gas Company under the supervision of the Manager of the former Company. The price will be 4s. 6d. per 1000 cubic feet on and after the 1st inst.; and it will be subject to a discount of 9d. per 1000 feet to consumers of 25,000 feet and upwards, and 6d. per 1000 feet to those burning less than this quantity, if the accounts are paid within 28 days.

DAMAGES FOR ANNOYANCE CAUSED BY ELECTRIC LIGHTING MACHINERY.—The Chancery Court of the County Palatine of Lancaster, sitting in Liverpool, was recently occupied for several days in hearing a motion for an injunction to restrain the Liverpool Electric Supply Company, Limited, from working the engines and machines at their supply station in Tithe-barn Street in such a manner as to annoy the plaintiff, a Mr. Pierce, an emigration agent and hotel proprietor, carrying on business at 13, Highfield Street, adjacent to the Company's premises. The plaintiff contended that the noise and vibration arising from the working of the machinery depreciated the value of his hotel premises, and seriously injured his own health and that of his wife and sister. For the defence it was contended that there was no nuisance. In the result, the Vice-Chancellor (Sir H. F. Bristowe) assessed the damages at £100, and directed the Company to pay the costs.

EXTRAORDINARY SEIZURE AT THE CLITHEROE WATER-WORKS.—Last Thursday week a firm of local tradesmen (Messrs. Bailey Bros.) went to the reservoir now being made for supplying Clitheroe with water, and seized the carts, horses, wheel-barrow, &c., for debt. Only a few barrows and spades were left; so that there will be a temporary stoppage of the works until fresh plant has been procured. The next day a meeting of the New Reservoir Committee of the Town Council was held relative to the seizure. On the advice of the Town Clerk, it was decided to make an effort to recover the property. The members of the Committee, accompanied by a number of policemen and Corporation workmen, accordingly went to Messrs. Bailey's premises, and took possession of the horses, carts, and implements seized on the previous night. Mr. J. H. Bailey, who was present, protested against the proceeding; but no forcible resistance was made. It is stated that the Corporation are entitled to the plant on the terms of an agreement entered into with the contractor.

CLAIM FOR DAMAGES THROUGH THE BURSTING OF A WATER-MAIN.—At the Waltham Abbey County Court, on the 20th ult., Mr. Warren, of No. 1, Forest Road, Loughton, sued the East London Water-Works Company for £39 2s., compensation for damage alleged to have been sustained by him owing to the bursting of one of their mains on Feb. 15 last. When the accident occurred, the water poured down the chimney and through the house, damaging the furniture and causing great inconvenience. For the defence it was contended that the Company were not liable, inasmuch as their pipes were well made, and were carefully tested before being laid. The Company's Engineer (Mr. W. B. Bryan, M. Inst. C.E.) explained the mode of testing the pipes; and stated that, notwithstanding all precautions, they occasionally burst, especially in the winter months. The pipe that gave way in the present case had been in use about 15 years; and when removed from the ground, the iron was discovered to have undergone a chemical change, which had rendered it soft. In his opinion, this change could not be avoided by the exercise of any reasonable care or skill. For the plaintiff it was argued that the pipes were under the defendants' control, and that therefore they were responsible for them. His Honour (Judge Abdy) thought the plaintiff had failed to adduce evidence of neglect; and consequently he gave judgment for the defendants, with costs.

THE CHARGES FOR WATER AT OLDHAM.—A deputation, representing some of the large consumers, waited on the Oldham Corporation Water Committee last Wednesday to ask for a reduction in the charges made to them. It was stated that the price came in some cases to as much as 1s. per 1000 gallons for all the water used in certain mills and factories; and a suggestion was made that, instead of taking the quarterly consumption, the Committee should charge for the yearly total, which would entitle some of those concerned to come on the very lowest scale. Some figures produced to the Committee showed that at Birmingham the charge up to 10,000 gallons was 1s. 6d. per 1000, and for 1,000,000 gallons it was only 6d. per 1000; whereas at Oldham up to 2,000,000 gallons it was practically 7d. per 1000. At Bradford, up to 400,000 gallons it was 9d.; beyond, 6½d. At Halifax, up to 70,000 gallons, 8d.; beyond, 6d. At Huddersfield, 7d. per 1000 all round. At Leeds, 6d. all round. The charge at Oldham was formerly as low as 3d. per 1000 gallons, when the consumers took a certain quantity; but the prices had gone up, and old mills were consequently unable to compete with the new ones. Mr. Waddington said it was unfair in some cases to make comparisons. At Leeds the cost of the water-works was nothing compared to Oldham. They drew their supply from a river; and it had never been known to fail. The Chairman (Alderman Buckley) said that when they made comparisons they had to take all the circumstances into consideration. When they charged 3d. per 1000 gallons they were losing a big amount annually; and they had a large sum handed over to them from the Gas Committee. The Committee adjourned the consideration of the subject.

THE BELFAST WATER COMMISSIONERS AND THEIR STONYFORD RESERVOIR.—In the Chancery Division of the High Court of Justice of Ireland, the Belfast Water Commissioners were recently plaintiffs in an action brought against the contractors for their Stonyford reservoir (Messrs. Anwell, Dyson, and Wainwright). The Commissioners were authorized by an Act of 1884 to construct a reservoir and other water-works at Stonyford, County Antrim, for increasing the supply of water in Belfast. The works were to be completed within six years. In May, 1886, the defendants put in a tender to execute the work for £39,905; and, the tender having been accepted, a contract was entered into by which the defendants agreed that the work should be completed in two years. There were other provisions by which the plaintiffs would have power to terminate the contract if the defendants neglected to carry out the works in accordance with the specification and to the satisfaction of the plaintiff's Engineer, or if, by delay or stoppage of the works, the Commissioners believed they would not be completed within the specified time; and that if the contractors failed to make good such a breach within six days after notice, the Commissioners might take over the works and plant. In June last year an interlocutory injunction was obtained to prevent the contractors from further interfering with the work, on the ground that it was not being done according to the terms of the contract; the plaintiffs undertaking to indemnify the defendants for any loss they might sustain if on the hearing of the action judgment was given in their favour. The trial was commenced on Wednesday; and it was expected to last three weeks. An arrangement was, however, come to, by which the Commissioners have agreed to pay the defendants £6000 in full discharge of their claim; the Commissioners to retain possession of the plant and material at the works, and all further proceedings to be stayed.

DEANHEAD WATER COMPANY.—This Company, which was registered on the 18th ult., with a capital of £10,000, in £10 shares, has been formed for the purpose of supplying water within the township of Stainland, Barkisland, and Elland-cum-Greetland, in the parish of Halifax.

IMPROVED VALUE OF TAR AND AMMONIACAL LIQUOR.—At the last meeting of the Darlington Town Council, Mr. E. D. Walker submitted a motion for the adoption of the minutes of the Gas Committee, containing a recommendation that offers which had been received for the tar and ammoniacal liquor produced at the gas-works—viz., £1,000 per annum for the latter and 15s. per ton for the former, for three years from Jan. 1, 1889—be accepted. In reply to questions, Mr. Walker said this price was about £450 better than the average receipts for the liquor during the past five years; and therefore the Committee deemed it inexpedient to erect plant of their own for dealing with this residual.

THE MANAGEMENT OF THE WARRINGTON GAS-WORKS.—A deputation waited on the Mayor of Warrington last Wednesday to ask him to call a public meeting "to take into consideration the recommendations of the Corporation Gas Committee with reference to the future management of the gas-works." The object of the deputation was to hold a meeting prior to the Council meeting to-day (Tuesday), in order that they might, in particular, get an expression of opinion adverse to the retention of Mr. J. Paterson's services as Consulting Engineer. The Mayor declined to call a meeting to consider the recommendations of a Committee which had not been submitted to the Council, but promised to lay before that body any resolution or petition which might be forwarded to him. It was stated by the deputation that the proposal of the Committee has excited a large amount of feeling in the town.

THE WATER QUESTION AT YEADON.—At the meeting of the Yeadon Local Board last Wednesday week, the Clerk (Mr. C. J. Newstead) submitted a draft letter he had prepared in reply to the communication read at the previous meeting of the Board from the Solicitors of the Yeadon Water Works Company. The letter was approved by a majority of the members present; and it was decided that a copy should be forwarded to the Local Government Board. Mr. Newstead, in his reply, dealt with each part of the letter which the Company's Solicitors had sent to the Local Government Board. He said the principal point raised was as to the validity of the award. The other points appeared to the Local Board to be immaterial, and more in the nature of an appeal *ad misericordiam* than real objections. He pointed out that the letter did not venture to assert that the award was invalid, but merely that the Company believed it to be so. After detailing the circumstances attending the arbitration proceedings, the Clerk said the Local Board contended that the award was valid and binding upon the parties. They submitted that it was good on the face of it, and that it must be taken to be binding until it was set aside by a Court of competent jurisdiction.

THE TRANSFER OF THE WINDSOR AND ETON WATER-WORKS TO THE CORPORATION.—On Saturday, the 23rd ult., the Windsor and Eton Water-Works were formally handed over to the Corporation of Windsor. The Directors of the Company had invited the Mayor (Mr. G. H. Peters), the Town Clerk (Mr. G. H. Long), and the members of the Water-Works Audit Committee to meet them at the works in Tangier Lane, Eton, where the ceremony took place. The works having been surveyed, the Mayor and members of the Committee were invited to partake of refreshments in the Board-room. Mr. K. Buckland, as Chairman of the Directors, proposed "The Health of the Corporation of Windsor;" and in the course of a few remarks, expressed a hope that the purchase of the works would prove a satisfactory transaction to the Corporation. The Mayor responded; observing that whilst differences of opinion on matters of this sort would always occur, the Corporation, in acquiring the Windsor and Eton Water-Works, had done what they thought would be for the interest and benefit of the town. Other speeches followed, and the proceedings closed. The works are now under the direction of the Audit Committee; Mr. Chapman, the Company's Manager and Collector, having been appointed to the same position at the works under the Corporation which he held under the Company. Last Wednesday evening, in commemoration of the Corporation having taken possession of the water-works, the Mayor entertained the members of the Corporation at dinner at the White Hart Hotel.

GWYNNE & BEALE'S PATENT GAS EXHAUSTERS AND ENGINES.

PLEASE ADDRESS IN FULL—GWYNNE & CO., ADDRESS FOR TELEGRAMS: "GWYNNGRAM LONDON."

HYDRAULIC AND GAS ENGINEERS, ESSEX STREET WORKS, VICTORIA EMBANKMENT, LONDON, W.C., ENGLAND.

TELEPHONE No. 2698.

Thirty-three Medals at all the Great International Exhibitions have been awarded to GWYNNE & Co. for Gas Exhausters, &c.

Only Medal at the Liverpool International Exhibition, 1886, for Centrifugal Pumping Engines.

They have never sought to make price the chief consideration, but to produce Machinery of the very highest quality.

The result is that in every instance their work is giving the fullest satisfaction.

They have completed Exhaustors to the extent of 24,000,000 cubic feet passed per hour, which are giving unqualified satisfaction in work, and can be referred to.

75 REVOLUTIONS PER MINUTE.

The above Engraving shows Two Engines driving Four GWYNNE & CO.'S PATENT NON-FLUCTUATING EXHAUSTERS, to pass 200,000 cubic feet per hour (without the slightest oscillation), at the EFFINGHAM STREET GAS-WORKS, SHEFFIELD

Can be made, when desired, on their New Patent principle to pass Gas without the slightest oscillation or variation in pressure.

NO OTHER MAKER CAN DO THIS.

GAS VALVES, VACUUM GOVERNORS, REGULATORS, PUMPS &c., &c.

Catalogues and Testimonials on application at the above address.

NOTICE TO SUBSCRIBERS

AS TO PAYMENT OF SUBSCRIPTIONS IN ADVANCE.

Subscribers who desire to avail themselves of the reduction in the Subscription to the JOURNAL by paying in advance for the second half of the year 1888, are reminded that this can only be done during the present month

The Subscription is at the rate of 21s. a year paid in advance, or 25s. if credit be taken.

TO ADVERTISERS.

ADVERTISEMENTS for the next number of the JOURNAL must be received by Monday, 12 o'clock noon, to ensure insertion; but as the Advertisement sheet of the JOURNAL is sent to Press the first thing on Monday Morning, Advertisers will please bear in mind that Orders for Alterations in or Stoppages of PERMANENT Advertisements should be received Not Later than Two o'clock on SATURDAYS.

THE JOURNAL OF GAS LIGHTING, WATER SUPPLY, & SANITARY IMPROVEMENT.

TUESDAY, JULY 10, 1888.

THE MONTREAL DISASTER.

In the present issue of the JOURNAL, we reproduce the very interesting pictures and description of the effect of the Montreal gasholder explosion which appeared in the last number of the *American Gaslight Journal*. The illustrations, which are from photographs taken from opposite sides of the wrecked house, convey a vivid idea of the scene of destruction; and although the accompanying letterpress is not all that might be desired, it must be remembered that it does not pretend to be the statement of an eye-witness. Probably most gas engineers who will look at the illustrations

will be able to see the occurrence distinctly enough without the aid of a "graphic" description. At the same time it cannot but be deplored that the only accounts of the disaster that have appeared in the newspapers, as well as this specially prepared notice, leave the most important question of all in the darkest mystery. Quitting this point for the moment, however, we may address a few observations upon the appearance of the wreck, as recorded by the faithful camera. The most striking thing about these pictures is the characteristic indication of the nature of the catastrophe which they present. The question has sometimes arisen in regard to an explosion, as to whether it was due to a gaseous mixture, or to gunpowder or dynamite. In the present instance, we have a typical gas explosion, the character of which is easily perceived. It was disruptive, as distinguished from shattering. The iron sheeting was rent like so much paper; and the girders were tossed about and twisted like matchwood. The gasholder-house was razed to the ground; but the destroying force was large, expansive, and equal in action. The bricks of the gasholder-house remained unbroken in heaps round the site where they had stood as walls. The roof was lifted up, rent, and then settled down on the ground. Much of the heavier scantling of the iron portion of the structure can be used again. It is not without a shudder that one can think of the men who were in and about the wrecked holder and house when all this mass of material was brought, in a flash, into the pictured condition; but, notwithstanding the damage done, a student of explosives would be justified in regarding this ruin as due to an essentially weak expansive agency. If the demolition had been deliberately brought about, with the provision that the structure was to be destroyed instantaneously without damage to surrounding property, it could not have been better done. The photograph which shows two other gasholder-houses in the background, does not indicate that the nearest of these to the wrecked house suffered any injury, although the first reports of the disaster stated that surrounding property was much damaged. We cannot even be certain that the windows, if glazed, were broken; but at any rate the sashes were uninjured. These characteristics are worth remembering in connection with the general subject of gas explosions.

With regard to the circumstances and cause of the explosion, the present account occasions some surprise. The affair happened on Saturday, May 26; and Reuter's telegram published in the English newspapers stated that "the building was undergoing repairs"—thereby leading anyone to infer that it was an old one, containing a gasholder that had been in use for some length of time. No further intelligence concerning the matter reached us until the paper from which the present account has been taken came to hand; and here we learn for the first time that the structure was a new one, and that the tank had not even been filled with water to its full capacity. This information is of grave import, since it leads one to ask how it happened that a gaseous mixture could find its way into a gasholder that had never been blown up with air for the usual test for soundness. Let us recapitulate the published statements. The tank had received 10 feet of water when it sprang a leak, and the water was pumped out again. The leak was stopped, and the water again turned in. But before it had "risen to any extent," the flow was stopped; and the Manager ordered the manlids to be taken off, in order that he might personally inspect the tank bottom. When only one lid was off, the fitter took it upon himself to enter the holder with a lighted lantern. He lowered a ladder down through the manhole, got on it, and dangled the lantern at the end of a cord below him into the holder. A survivor who witnessed the action and whose testimony was taken "while he was writhing on his bed"—this is a touch of "graphic" writing in the American manner—says that he thereupon covered his face with his hands, because he knew what was coming. The explosion duly followed, and justified the witness's prescience. The man who fired the gas was killed, with four others; and five men were more or less seriously injured. The coroner's jury returned an utterly inconclusive verdict, from which we gather that the inquiry into the cause of the death of these men was conducted in a very perfunctory fashion. They found, of course, that they were killed by a gas explosion, and that one of them ignited the gas in his ignorance and imprudence; but beyond this the jury apparently could not go. The verdict seems to have satisfied the requirements of the law; but the whole story does not satisfy engineers, who naturally want to know how the gas got into the holder. The man who introduced the lighted lantern into the holder was rash perhaps; but his

imprudence would have been harmless except for the mismanagement, carelessness, or what it was, that allowed the gas to accumulate in a new holder standing in a tank containing very little water.

We are told that all the connections had been made, and that the inlet-valve was perfectly tight, while the outlet-valve "leaked slightly." It is remarked, moreover, that "the pipes" were said to be water-sealed." Here is the mystery. Our American contemporary, with great amiability towards the chiefs of the Gas Company's staff, observes that the fitter "had no fear that gas had escaped into the holder;" but such assurance is not to be allowed for a minute to go for anything in an attempt to extenuate the act of the "unfortunate" who fired the gas with the lantern. We hold that the responsibility for rendering such a disaster impossible did not rest with the fitter, but with the official in charge of the work in hand, whoever he might be. We have not had the advantage of seeing the full report of the examination of witnesses at the inquest; and therefore refrain from making any allegation. If the inlet and outlet syphons were sealed with water, as they ought to have been, it is scarcely too much to say that such an explosion as this could not possibly have happened. No gas manager or gasholder maker will believe that at Montreal or anywhere else gas goes wandering about through the air or in the ground, seeking entrance into a brand-new holder. If the holder had been an old one, or the water in the tank had had gas standing over it, as in the case of an old tank, the sole responsibility for hazarding a naked light inside the holder would have rested with the man who did the rash act. Men will be foolish sometimes, notwithstanding all rules, discipline, and experience. Seeing how often candles and lanterns are required inside new gasholders, however, before they are tested with gas, it would be outraging common sense to lay down the proposition that there is more risk in taking a candle into a gasholder under such conditions than into a steam-boiler. It is beyond the possibility of question that gas *did* get into this new Montreal holder; and it is impossible to get away from the query *how*? There is enough in the latest information (meagre as it is) to enable any gas engineer to form a pretty shrewd opinion on this point. It appears that the tank had been nearly half filled with water, and had been emptied again. The manholes were closed; so that there was no possibility of escape for any of the gas that found its way inside through the inlet or outlet pipe. A little water was then put into the tank—sufficient probably to seal the bottom of the holder; and then the manufacture of an explosive mixture went on until the whole inner lift was charged with it. We are told that the outlet-valve leaked. But, how did this fact become known? We should not be disposed to ask many more questions than this in order to clear up the mystery as perfectly as it is likely to be cleared up in this world.

The whole occurrence remains enshrouded in an atmosphere of doubt, which cannot be regarded as satisfactory to anybody. There should be no more mystery about gas explosions than there is about railway "accidents;" and it is doing an ill-turn to the gas industry to attempt to hush them up under the pretence that they are inexplicable by natural means. It is bad enough as it is, when the law gives residents of a district unnecessary rights of protest against the construction of gasholders in their vicinity; but matters are likely to be worse if the idea once gets abroad that new gasholders, never used for storing gas, are likely to blow up without notice, and without blame to anybody but an unfortunate fitter. The public are getting rid of the notion that railway accidents are due to signalmen and drivers, and are increasingly disposed to look higher for the personal causes of disaster that are preventible by the exercise of human foresight and care. So in the Montreal gas-holder case. We ask if the supervision was right; if the discipline of the works was perfect; and if an experienced engineer was in charge of the station, and of the new gas-holder. If there was such an officer, he should be called upon to explain how gas got into the new holder, or at any rate to prove that every precaution that could have been desired was duly taken against such a result. If there was no such official, then the Directors of the Company stand morally convicted of the gravest dereliction of duty which men in their position can commit. We have no desire to be unduly severe upon the Directors and higher officials of the Montreal Gas Company in respect of a deplorable occurrence which must have brought considerable trouble and sorrow upon them, apart from the money loss, which is great. At the

same time, regard for justice compels everyone who is able to look below the surface of statements relating to disasters of this order to speak out when, as in this instance, the record is not so clear as might be desired. It would have afforded us infinitely greater pleasure to have been able to declare that the Gas Company and their officials did everything in their power to render such an occurrence impossible, and to clear up the cause after it had happened. It may yet be possible to say the former, if the questions suggested by the imperfect account published by our American contemporary can be satisfactorily answered; but the wording of the verdict of the Coroner's jury forbids us to concede the latter.

THE SENTENCE ON SAMUEL HUNTER.

On Friday last, Samuel Hunter, formerly the Manager of the Salford Corporation Gas-Works, was sentenced by Mr. Justice Hawkins, at the Central Criminal Court, for the crimes to which he pleaded guilty at the March Sessions. The air of sensationalism that has surrounded the deplorable affair from the first was kept up to the last act of this drama of real life; for the first thing the Judge did, upon the case being called on, was to throw down to the Counsel engaged a packet of newspaper cuttings, relating to the reasons for the postponement of sentence, which appeared to have been sent to him from the office of the Town Clerk of Salford. No object for this communication was assigned or imputed; but the Judge protested with much emphasis against any attempt to subject him to the supposed influence of public opinion, if this was contemplated. It would be idle to deny, however, that an idea has been prevalent that the prisoner was being treated differently to ordinary persons in a similar position, and that the sentence had been deferred with a view to the possibility of his making restitution of some of the money of which he had defrauded the ratepayers of Salford. Indeed, it will be seen, by referring to the report of the trial appearing in our issue for March 27, that sentence was purposely deferred to await the issue of Chancery proceedings that were stated to be then pending—not, so far as can be understood, that the question of restitution could be held to affect the sentence, but for fear lest sentence should interfere with the civil proceedings, or any more expeditious arrangements for settlement that might grow out of them. The question that has most interested the people of Salford, and others who have watched this case during the past three months, has undoubtedly been whether any restitution has been made; but now the criminal part of the affair has been concluded without disclosing anything definite respecting its financial side, except that the civil proceedings are still dragging their slow length along, and that no money has yet been paid or promised by the prisoner. Interest to-day, therefore, centres once more in the sentence, which has been pronounced after all as though there was no question of restitution of illicit gains. The nature of the transactions of Friday may best be gathered from our special report; and we shall not attempt to enlarge upon the facts here. For the perjury committed in connection with the trial of Mr. Ellis Lever (which, as described by the Judge, was a crime of a very heinous order), sentence of five years' penal servitude was pronounced, to date from the day of conviction. For the other charges of the indictment, a concurrent sentence of one year's imprisonment, with hard labour, was entered. We do not offer any comment upon the oration with which Mr. Justice Hawkins prefaced his severe, if just sentence. Judges have their own standards of what is necessary, useful, and appropriate for such occasions; and it is idle to criticize them. Of more immediate interest, because of wider application, than the moral reflections addressed to the prisoner personally are the expressions employed by the Judge with reference to the "commission" system of which Samuel Hunter was a victim. Referring to the single case of the prisoner's dealings with Messrs. Pope and Pearson, Lim., Mr. Justice Hawkins said:

There can be no doubt that it was a very dishonest bargain, because if a person who is employed to buy from those who are to serve his employers insists upon having a commission upon the goods supplied, it makes it absolutely certain that those who have to supply the goods sell them at a dearer rate than they would do if no commissions were paid. In truth, it is depriving those who buy of the amount of commission which is paid to their servant. *I take this to be in itself a very dishonest course of dealing; and I am perfectly satisfied that you must have known, at the time you were receiving the various cheques that were paid to you, that it was so.*

Herein is our justification for all that has been published in these columns in denunciation of the "commission" system. With this extract, condemning the wrong which the unfortunate Samuel Hunter committed, we would fain conclude our remarks upon the fate that has overtaken him. We cannot, however, withhold an expression of pity for the

man; for, whatever his faults, his punishment is surely sufficiently severe to evoke a feeling of commiseration in all who acknowledge a common humanity, and recognize how little really divides the best of us from the worst.

THE INSINUATIONS AGAINST THE HALIFAX GAS ADMINISTRATION.

IN last week's issue of the JOURNAL we printed from the local papers some correspondence that had passed between the Town Clerk of Halifax, Mr. Ellis Lever, and Mr. T. Fox, of the Silkstone Coal Company, respecting certain coal contracts of the Halifax Corporation Gas Committee; and also a paragraph from the *Pall Mall Gazette*, and letters relating thereto from the Editor and the Town Clerk. This paragraph contained a very ugly insinuation of the possibility of disclosures in Halifax, "if the parties concerned dared to court inquiry," of something similar to the Salford malpractices. It was with much reluctance that we gave additional publicity to this matter. But the duty of a journalist is imperative; and we could not minimize any damage that might be done by an *ex parte* statement by restricting its circulation. The responsibility for all such statements rests with their originators. In the present case we have no hesitation in connecting the innuendo of the *Pall Mall Gazette* with Mr. Ellis Lever's high-flying protest "in the interests of fair and honourable trading," and the latter again with Mr. T. Fox's threat of a copy of the Salford scandal to be repeated in Halifax. The correspondence has now been completed by the letter from Mr. Ellis Lever which appears in another column; but it is happily possible to remark that this matter is not likely to end with the correspondence. If the letters and the newspaper article meant anything at all, they conveyed a distinct imputation upon the integrity of the Halifax Gas Committee and their Engineer and Manager, Mr. William Carr. Mr. Carr was at the time one of two selected candidates for the vacant post of General Manager of the Nottingham Corporation Gas-Works; but the Nottingham Gas Committee rejected him solely and expressly on account of this imputation upon his character. This is specific damage for which it is to be hoped somebody will be made to pay smartly. The *Pall Mall Gazette* has played a shameful part in this business, and will probably be taught a sharp lesson upon the subject of the danger of throwing about fire-brands in the shape of base insinuations. As to Mr. Ellis Lever, the least said is the better. His last letter is a transparent attempt to back out of his responsibility. But we are not disposed to indulge in comments upon a matter that must be dealt with judicially. Everybody will sympathize with Mr. Carr and the Halifax Gas Committee; but if the processes of law enable them to punish their assailants as the latter deserve, good will come out of evil, and the taste for innuendo specially directed against gas officials, which has lately been developed in certain quarters, will receive a salutary correction.

END OF THE COAL AND WINE DUES CONTINUANCE BILL.

THE hopeless attempt to perpetuate the London Coal and Wine Dues in the interest of the Corporation of the City and the Metropolitan Board of Works has at length been abandoned. The order for the second reading of the Bill for continuing the dues was discharged on Monday last week; and thus ended the forlorn hope of the Metropolitan Local Authorities. The impost is an old one; but it is not on any account venerable. It has long been an irritating hindrance to the natural development of the manufacturing interests of the capital; and it has accordingly been impossible to smile at an anachronism which, however absurd, yet retained the property of mischievous action in such a high degree. People laugh at the Lord Mayor's procession, and at some other of the harmless, if useless and not particularly edifying usages of the civic system; but there are points at which good-humoured tolerance yields to silent disgust, and this again to active protest. In the case of the Coal Dues, the incurious tolerance of the great mass of the population of London, upon which the municipal authorities largely relied in their attempt to perpetuate a bad old custom, has proved insufficient to support them under the determined onslaught of the clear-sighted enemies of the dues. The history of the now successful movement for putting an end to the customary taxing of coal consumed in the Metropolis is a very instructive story of the triumph of principle against expediency and self-interest. Everything appeared to favour the Corporation and the Metropolitan Board of Works, who shared the proceeds of the dues between them, when they began to move in the matter of

securing the continuance of the custom. It had been established for such a long time that everybody took it as a matter of course. The great bulk of coal consumers could not be said to feel it; and not many of them even knew of its existence. It was a tax easily and cheaply collected; and the proceeds had been applied for purposes admittedly beneficial to the Metropolitan community. Finally, and as a clinching argument, the ratepayers of the Metropolitan area were told, with terrifying emphasis, that if the dues were not renewed, the rates—that bugbear of the town resident's existence—would inevitably be increased by the dreadful increment of 3d. or 4d. in the pound. All this made a good solid body of argument in support of the dues; but the first approaches of the Metropolitan Authorities to the Government of the day, for the purpose of eliciting a promise of a renewal of the help that former Governments had extended, when the question of continuing the impost had been mooted, met with a decided check. The authorities were disappointed, but not discouraged. They thought the refusal of their request proceeded from a Minister inspired with too high a regard for the pure ethics of Free Trade, and possessed with a *doctrinaire* dislike of indirect taxation. They thereupon decided to wait for a change in the Administration before raising the question again; but meanwhile they endeavoured to gain outside support. They approached the House of Lords with one tale, and the ratepayers with another. A Ministry having succeeded to power which it was thought would not cherish a too pedantic esteem for Free Trade principles, they approached the Treasury with their petition for assistance; but, to their amazement, their reception was infinitely worse than it had been before. A frantic attempt to manufacture public opinion followed, and ignominiously failed. Then a glittering bribe of a share of the plunder was offered for the parliamentary aid of representatives of the suburban constituencies; and by this means a contingent of members, respectable at least in number, was marshalled in support of the Bill for the continuance of the dues which, as a last resource, was submitted to the House of Commons in the present session. It has all been in vain. The ratepayers have made no sign of desire for the Bill; and, to finish the matter, the Metropolitan Board of Works stand convicted at the bar of public opinion of unfitness for the charge of public funds, especially when derived from a source independent of the ratepayers. So the dues will die, and London will have cheaper coal, gas, and coke; and a great temptation to unwise and extravagant expenditure will be removed from the administrators of its local affairs.

THE MANAGEMENT OF THE NOTTINGHAM CORPORATION GAS AND WATER UNDERTAKINGS.—At the meeting of the Nottingham Town Council on Monday last week, the following report of the Gas Committee was adopted:—"That they have received from Mr. Wright, the General Manager, his resignation of the office he holds under your Committee. As it is urgent that the position should be filled up as early as possible, the Committee have advertised in the usual manner for a successor. They have offered the salary of £600 per annum, the amount paid to Mr. Wright when he first entered the service of the Corporation. Your Committee are of opinion this is a proper sum. The Committee cannot close this report without expressing their great regret at the loss of Mr. Wright's services, and their high estimation of his character and skill." As stated in another paragraph, Mr. W. R. Chester, of Manchester, has been appointed to the vacant position. On the same occasion, Alderman Gripper moved the appointment of Mr. L. T. Godfrey Evans, of Liverpool, as Engineer of the water undertaking, in place of Mr. Wharton, resigned.

SOCIETY OF CHEMICAL INDUSTRY.—The annual meeting of this Society was held last Thursday, in the Bute Hall of the Glasgow University, under the presidency of Professor Dewar, F.R.S. The General Secretary (Mr. C. G. Cresswell) submitted the report of the Council on the year's transactions. It stated that 209 new members had been elected, and 116 removed by death, resignation, and other causes, showing a net gain of 93. The total number of members was 2395. The papers read before the various Sections had maintained their character for general usefulness. The finances of the Society showed an ample surplus to provide for contingencies. On the 22nd of June last, the Treasurer reported that the Society had £2088 11s. 9d. invested, and £1761 12s. 9d. in the bank, as against £1039 10s. 4d. invested, and £1500 18s. 9d. in the bank, at the time of the previous annual meeting. Under these circumstances, the Council felt able to make some addition to the salaries of the Editor of the Society's *Journal* and of the General Secretary. The Secretary further intimated that that morning some new members had been elected, which brought the membership up to more than 2400. The report was adopted. The President then delivered his Inaugural Address, in which he dwelt on what had been done by Scotland in stimulating the theory of chemical action. Mr. Ludwig Mond was elected President for the current year; and it was decided to hold the next annual meeting in London.

The Gas Institute.

PROCEEDINGS AT THE TWENTY-FIFTH ANNUAL MEETING.

CHARLES GANDON, Esq., M. Inst. C.E., PRESIDENT.

PAPERS AND DISCUSSIONS.

(Continued from p. 19.)

[Owing to the illustrations to accompany Herr F. Lux's paper on "The Newest Forms of the Gas-Balance" (which followed that by Mr. Henry Woodall, given last week) not reaching us in time, we are compelled to defer till next week the publication of his communication. In the meanwhile we give Mr. Somerville's paper; and shall complete the papers and discussions in our next issue.]

THE VENTILATION OF GAS-LIGHTED ROOMS.

By JOHN SOMERVILLE, of London.

The ventilation of gas-lighted rooms is a question of the greatest importance when considered in connection with our special industry; and although the matter is beginning to be better understood than it formerly was, and more interest is attached to it, and ventilation is now regarded as a necessary of civilization and as an accompaniment of all well-lighted and properly heated rooms, yet there is still a vagueness and a rule-of-thumb manner of applying it to our houses—a sort of haphazard, come-as-you-like kind of way of letting in the external air, and getting rid somehow or other of the vitiated atmosphere of our living-rooms.

We are all conscious of the necessity and the importance of breathing pure air; and how it affects our health and very existence. What is more exhilarating and delightful than a brisk walk through the pure country air in an early spring morning; its agreeable freshness and reviving influence is greatly conducive to our pleasure, comfort, and well-being. This is the sort of influence we want imported into our homes; and although it may be very difficult to get pure country air into rooms in large towns, we ought to put forward our best endeavours to provide in them as much fresh air as possible. I am afraid that, even in this enlightened age, very many persons are not aware of the great necessity there is for thorough ventilation—or, as the JOURNAL OF GAS LIGHTING calls it, "Aërial sanitation," which, I think is a much better term when used in reference to dwelling-houses, halls, and theatres—because in their great anxiety to exclude cold and damp and the inclemency of the weather, they prevent, as much as they can, the external air from coming in to renew the atmosphere inside, which is essential to prevent its becoming stagnant, and consequently unfit to support human life. Our lives can be preserved for some time without food or water; but take away the air we breathe for only a very short space of time, and we cease to exist. We must have air; and it must not be the air breathed only 2 or 3 minutes before, but totally different, and fresh. As, by the laws of Nature, life is supported by the air, and as only about one-fifth of the ordinary atmosphere, or oxygen of the air, is capable of sustaining life, the rest, or the nitrogen, serves as a diluent to render the air more fit for respiration. At every breath, we inhale about a pint of air; and we breathe about 18 or 20 times a minute. In the lungs there is an admirable arrangement, by which the air is exposed to the action of the blood, which changes the vital air, or the oxygen, into carbonic acid, which is destructive of all animal life; but by a beautiful provision of Nature, in order to prevent this carbonic acid—this exhausted, contaminated, and now poisonous air—from being used a second time, while it was in the lungs the vital air takes up so much heat as to lessen its specific gravity, and it is so light as we breathe it out into the atmosphere that it rises at once above our heads. I may also remark here that we have learnt, within the last few years, during a noted controversy, how quickly air is heated, and likewise how quickly it gives the heat up again. In occupied rooms, the carbonic acid, as it is exhaled, rises between each breath to the ceilings; and a fresh and pure draught of air is thus secured each time we breathe. By the care, however, that some people take to prevent the entrance of external air, they are compelled to breathe over and over again, the same contaminated atmosphere.

To those who have experienced the grateful and refreshing effects of the sweet and pure morning air, there is little wonder at the lassitude, languor, and want of energy they

see consequent upon the continual breathing of a foul atmosphere in over-crowded and ill-ventilated rooms. It is perhaps a matter to be thankful for that the doors and windows now fixed in most modern houses are made at so much a dozen, by the "sweating system," from not over-dry and seasoned timber, as used in houses now-a-days by builders; so that a tolerable quantity of air finds its way into the rooms through the chinks and crevices of the woodwork, which satisfies the mind of the builder that he has thus provided sufficient ventilation, and that the fireplace and chimney will do the other part of the work. He also takes care, in laying the flooring-boards, that the materials shall not be too well seasoned, so that there shall be sufficient shrinkage before anyone occupies the house to allow of a $\frac{1}{4}$ -inch space between each board for air to enter to supply the fire with the necessary quantity, and at the same time causes the sensation of being at sea, by the heaving up and down of the carpets during sudden gusts of wind in stormy weather. Besides this he sometimes provides an iron grating, as a riser, at the front doorsteps, which admits light and air to the cellar; and from there the air finds access to other parts of the house. If it were not for these rough-and-ready means of admitting fresh air into houses, the majority of them would scarcely be habitable during winter time. No provision, however, other than the ordinary fireplace, is thought of for the exit of the vitiated air of the rooms; and anyone entering a room in the evening, after it has been occupied for a few hours, is met with a hot blast of impure air, at 5 or 6 feet above the floor-level—owing to the vitiated atmosphere not having descended low enough to come under the influence of the draught in the chimney. The occupants of the room are therefore sitting in a bath of hot, polluted, unwholesome air, which is such a fruitful source of coughs, colds, fevers, and disease.

Architects and designers of houses do not seem to attach sufficient importance to the aërial sanitation of our common dwellings; but if a hall or other large public building is to be erected, as a rule some means of ingress and egress for air are thought of, and an elaborate system of mechanical ventilation is arranged for, with the result of creating unbearable draughts, caused by the large volumes of cold air which is poured into the rooms or chambers haphazard, and which is allowed, or is supposed, to find its way out by the windows placed high up in the building, or other openings and chinks in the woodwork of the roof. Then these gentlemen appear to favour electricity for lighting, because they say such lights do not give off any heat, and so do not vitiate the air—forgetting or ignoring the fact that the heat evolved by a gas-flame is the best of all ventilating mediums, provided they would only arrange for a simple means of conveying the products of combustion out of the room—thus securing light, heat, and ventilation in the most perfect degree, and without a tithe of the first cost and expense of annual maintenance of the more elaborate system.

As a rule, architects do not yet recognize the necessity of providing for a constant change of air in the living-rooms of dwelling-houses, clubs, and hotels. They go on designing and building in the old groove, except when some special case requires a means of ventilation, or necessity points to some effort in that direction. Then they seem to think that it is quite sufficient if they arrange for a few air-bricks outside, and a hole in the wall near the ceiling, with a flapping arrangement on the inside, and a similar opening into the chimney; so that when one opens the door of the room, these things, like burglar alarms, set up a clatter if they are not put out of action, as they are very frequently, because of the downpour of cold air on to the heads of the inhabitants of the rooms or offices in the winter time. In summer, however, when the outside air is warmer, they are permitted to act, and the noise is tolerated, as they afford an opportunity of procuring a change of air in the rooms, when there is no fire to set up a circulation, and take the vitiated air away. Really, therefore, upon gas engineers and managers is thrown the onus of supplying means, or suggesting arrangements, for carrying away the products of combustion from rooms lighted, or about to be lighted, by gas—a duty which properly belongs to architects and builders, but who too often, to cover their own shortcomings or apathy, or want of invention in providing for the inlet and outlet of the air, do not trouble themselves much about it. No doubt there are obstacles and difficulties at times in the way, which seem to be too formidable to overcome by uninitiated and inexperienced men; and they, to get over the trouble, often recommend the electric light as a panacea. It is therefore the duty, as well as to the interest of all gas men to try and help, and, if possible, show these

men that the best and most approved means of ventilation is by gas-lights—that wherever a gas-light is fixed, a current of air is established, which only requires a little thought, and the exercise of a modicum of common sense, to use it for providing a constant change of air in any room, and so arranging for by far the best and most approved means of ventilation possible.

It is idle for us as gas engineers to ignore the fact that there is a widespread impression as to the use of gas in dwelling-rooms, &c., contaminating the air, and that the products of combustion from gas-lights destroy its purity, injure books, hangings, furniture, and plants; and it is downright affectation to pooh-pooh the arguments used, and to say: "Oh! nonsense; there is nothing in them, and the use of gas is no more unhealthy than any other illuminant." No doubt that is so; and according to Dr. Letheby's very instructive experiments (which will be found in the back numbers of the JOURNAL OF GAS LIGHTING, and need not be detailed here), as compared with candles or oil giving an equal illuminating value in any large or small room, gaslight vitiates the air to a much less extent. For instance, a common batwing or union-jet burner is credited with only about 4 per cent.; while oil stands at 11 per cent.; and candles at 13 per cent. Now we have ventilating gaslights standing lower still in the scale, or at only 2 to 2½ per cent. There is also to be considered the sulphur "bogey," which has been, and is still, greatly and grossly exaggerated; and it has not yet been thoroughly determined—because chemists, like doctors, disagree on the question, and have a difference of opinion—whether the harm done to books, &c., is really caused by the products of sulphur emanations, or by highly-heated carbon compounds. The latest theory, I believe, is that it is not due to the small amount of sulphur in the gas at all, but by what some chemists call carbon oxy-sulphide, or some compound of carbon—something not yet very well understood—condensing on any object a foot or so below the level of the ceilings, and which I will define in every-day phraseology, and free from any chemical ambiguity, as the senseless retention of a stratum of very highly heated aqueous vapour, 1 or 2 feet deep near the ceiling. Prevent this from accumulating, and you at once prevent the depositing of moisture on any objects 2 feet from the top of the room; and no harm can or will be done any more than if a dozen sperm candles were burning, and their products carried away in a similar manner. If there is injury, it indicates very plainly the want of, and the necessity for, an efficient means of ventilation to carry away these heated aqueous vapours and hot-air products; and if this is done, there will be pleasant and healthy rooms to live in. This is the best argument to use; and if we can supplement it by showing how to do it, and by pointing to examples, and saying "Do likewise," a great advance will be made.

All ventilating arrangements must and should be simple, and not expensive for the average householder to adopt. We know it has been suggested to put a number of jets in a tube, and carry the tube outside, terminating in a cowl or some other creaking arrangement; or put a solid flame Bunsen burner in a box in the ceiling under the flooring-boards, and carry a tube between the joists to the outside to exhaust—or, as described by some elementary writers "to suck" the vitiated air from a room. But, in my opinion, these means are too artificial. It requires only some natural aid; and, even in the matter of ventilation, the nearer we can copy Nature the better. Some also advocate admitting air at the ceiling-level to fall down to the floor, carrying with it—so they say—the vitiated air (we must put a big "Qy." to this); and then taking the air out at the floor-level. Others say let the air in at the floor-level behind the skirting boards of the room, and let it out into the chimney at the level of the ceiling and by the fire. But these appear to me to be what I must term "unnatural" schemes, which must be very unsatisfactory, and sure to end in failure and discomfort.

Some two or three months ago, I had an opportunity of seeing in action the latest improvement in artificial ventilation, known as D. C. Green's ventilating system. This consists of an air compressor driven by a gas-engine situated in the basement of the building to be ventilated, or in any position adjoining the building. The compressor supplies air at a pressure of from 3 to 5 lbs. per square inch, which is conveyed in small pipes similar to a house fitted with gas-pipes, and an automatic multiplying air nozzle fixed at or near to any place where the ventilation may be required. The air from these nozzles causes a large secondary or induced current to flow through a specially-shaped pipe or

orifice from the external air; and this secondary air current is some 20 to 30 times greater in volume than the amount of air coming from the nozzles. They can be fixed in any part of a building or rooms, and made to draw fresh air from any convenient place by a continuous light sheet-iron or wooden pipe from the special orifice to the outer air; and they can carry it forward and deliver it exactly when required, or distribute it in any direction. For exhausting foul air from a room, by reversing the direction of the nozzles, the impure air is drawn out, and ejected to the outside of the building. Where necessary, there can be one of these nozzles fixed for the delivery of fresh air, while another one is drawing out the vitiated air; so that the air of any room can be changed every five minutes if required. A great advantage in this arrangement is that the air can be supplied either warmed to any desired temperature in winter, or cooled to a pleasant degree in summer time. One of the nozzles, discharging 80 to 90 cubic feet of air per minute from the compressor, delivers at the other end of the special orifice about 2000 cubic feet per minute, which comes entirely from the outer air. In the absence therefore of any natural means of ventilation, here is an admirable system for renewing air by artificial means, applicable to all buildings, and at very little expense, or only a few pence per day in these times of cheap gas.

My first experience in the matter of ventilation was in 1852, when assisting in placing three large sun-lights in the news-rooms at Wolverhampton, for the purpose of lighting and ventilating, and renewing the atmosphere of the place, which was a thing greatly needed in that centre of the then smoky Black Country. They were most successful in doing this; and I believe this was one of the first attempts at introducing sun-lights for the purpose of ventilation. The centre-tubes were carried only about 5 or 6 feet above the level of the ceiling; and the heated air diffused itself perfectly in the space between the ceiling and roof, and found its way out through the over-lapping of the slates. As the tubes were not taken outside the roof, no cowl or butterfly valve was necessary, as gusts of wind did not reach them nor affect the draught in the tubes. There was therefore no down or back draught to interfere with their action; while the current of air rushing up the 6-inch centre tube was sufficient to carry a piece of cloth several feet up into the air. My next experience in this matter (in conjunction with Mr. Keeling, the architect of the Strand Music Hall, now the Gaiety Theatre) was in 1862, at which time I was Engineer of the Maidstone Gas Company. A glass ceiling had to be illuminated, and the ventilation of the Music Hall provided for. Two 500-light meters were fixed in the basement; and two 3-inch rising mains went to the roof, where there were a double row of sun-burners, about 2 ft. 6 in. above the ground, and stained glass which formed the ceiling; the centre tubes passing to the outside of a glass-covered roof, as the heat was too great, owing to the large number of burners, to allow it to remain inside. The end of the tubes were protected from the winds and weather by cowls. The ventilation was provided for by the panes of glass forming the ceiling being supported on clips in iron frames; thus leaving a margin of ⅜ inch between the panes and the frames for the passage of air from the hall, which also supplied the sun-lights. By this means perfect ventilation was secured, without draughts; while the hall was never over-heated, because of the absence of all gas-lights from it; and the change from daylight to darkness outside was imperceptible by the audience inside. This is an excellent method for ventilating and lighting any large hall.

My next special acquaintance with ventilation was in 1866, when I undertook the lighting and ventilation of Moat Park House—the residence of the Earl of Romney, about two miles out of Maidstone. His Lordship made it a *sine qua non* that the introduction of gas to his mansion should be accompanied by ventilation, so that all products of combustion from the gas should be conveyed away. I engaged to do this with some amount of fear and trembling; for I had failed in one or two small matters in the way of ventilating gas cooking stoves and gas fires, which had to be removed on account of the smell. But cooking-stoves in those days were not so perfect as they are made at the present time; although I must say some of them smell rather strongly now at times, when one enters the house of a friend, it is quite possible to intimate to him that he has a gas cooking-stove in action, because of the smell given off by cheap and imperfect atmospheric burners. A good and properly constructed Bunsen burner does not offend the nose very much; but

those attached to the cheap class of cooking-stoves are often very offensive. It is no uncommon thing to hear the remark: "I should like to have a gas-stove; but I cannot stand the smell of them." I am under the impression that these stoves would be more generally used if makers would take care and fit good Bunsen burners to them, as I have found that the ventilation of a gas-stove—i.e., carrying away the fumes—is in very many cases a very difficult matter to deal with. A hood, with 4-inch pipes running into the nearest chimney, will not always accomplish it; nor a 6-inch pipe, carried through the roof of the scullery, with a cowl fixed on, does not always answer the purpose. To prevent complaints always recommend those stoves which do not offend the nose. But this is a digression. As I was saying, I undertook to carry away all the products of combustion and the vitiated atmosphere from the rooms of Moat Park House, especially from the library, which was a fine, large apartment, occupying one-half of the South front of the house on the ground-floor; and it contained a splendid collection of rare and costly books. There were three fire-places in the room—one at each end, and one in the centre—with the old-fashioned andirons for burning logs of wood; no coal being allowed to be burnt in this room. The ceiling was panelled in three divisions; and so was suitable for three sunlights. These were inserted by cutting out part of the centre ornament, and fitting in strong galvanized iron boxes, double-cased; a 4-inch pipe being carried into each chimney between the joists. The ventilation of this room was perfect; as was also that of the other rooms, which were treated in a somewhat similar manner. Where chandeliers were used, the centre flower of the ceiling was perforated with a sufficient number of small holes, so as not to be noticeable from the rooms. A zinc box was then inserted over these holes under the floor, and between the joists; and a pipe conveyed the vitiated air and products of combustion into the chimney.

The only difficulty I met with was in his Lordship's private library, which was at the back part of the house, and with a northern aspect. It was lit with a large-sized Winfield's Argand library-lamp, with opal reflector, which was much in vogue in those days, and with the usual perfumage or smoke consumer or distributor, which was then almost a necessary adjunct to Argand burners; for the more scientific "London Argand" had not then been introduced. With the old-fashioned Argands, when a door was suddenly opened, they would smoke unless turned down low.

Well, the ventilation of this private library was a little troublesome. A 4-inch hole had been made in the ceiling, and covered by a stamped brass centre ornament 10-inches diameter. A zinc box between the joists collected the heated air, which was conveyed to the outside, as it was difficult to get to a chimney. The end of the 3-inch pipe was protected by a cowl; but there was occasionally a back draught, caused by a projecting wing of the building, which, when gusts of wind came, created eddies or gave a whirling motion to the outside air, causing the air in the eduction tube to strike back. This was at last overcome by placing in the end of the pipe a light flap-valve hanging slightly out of the perpendicular; so that the slightest breath of wind from the outside caused the valve to close against the opening of the pipe, but only for an instant or so, and not long enough to interfere with the ventilation—for, if any accumulation of heated air took place, it was only for the moment, and directly the valve was released, the proper action went on.

You will perhaps pardon me for entering into these minute details; my only object in doing so is that you may be enabled to give instructions to your foremen and fitters, when little difficulties of this kind crop up, how to overcome them. These little troubles will crop up in most all ventilating arrangements, and they are sometimes very perplexing. A peculiarity in ventilation is that an arrangement which is perhaps successful in a dozen cases, will in the thirteenth, although exactly the same means may be employed, be unsuccessful through some little obstruction—for instance a bend or an elbow too many, or in the wrong place, or some little flaw overlooked. Besides what may answer in a southern or western aspect will not always be suitable when applied to a northern or eastern look out. I would advise that ventilating flues such as I have described should always be taken into a chimney, where possible; and then, if the chimney is properly constructed, there will be a pull of $1\frac{1}{2}$ or 2 tenths of an inch vacuum, and never any back or down draught. Two-tenths constant pull

is sufficient in all cases to properly ventilate the largest room, provided the eduction-pipes are large enough to convey the whole of the products of combustion and vitiated air into the chimney.

I will now describe my latest efforts in ventilation. Some three years ago, I had occasion to assist in designing a dwelling-house about to be built; and I thought this a good opportunity of practically carrying out one's theories on the subject, and to see if it were possible to make practice square with theory, or *vice versa*, in the matter of ventilation. The object I sought to obtain was that the temperature of the air in the rooms should never at any time be more than 10° higher at a foot from the ceiling than a foot from the floor in the winter months of the year. For dwelling-houses in the summer months may be left to take care of themselves, as we all know ventilation is a simple and easy matter during the dog days. In the course of some experiments I made a few years ago in regulating the secondary air required for generating furnaces, I found that 2-10ths of an inch draught gave a velocity of air of about 6 feet per second; and from this data, I calculated the area of opening required for admission and eduction of air into and out of the rooms. Taking into account the natural pressure of the air as possessing an ascensional force of 1-10th of an inch for every 10 feet in height, the quantity of air needed every quarter of an hour was found; and, in order that there should be no stoppage or obstacle to prevent a constant flow of fresh air into each room, whatever winds or weather prevailed, I required it to be warmed, or warmer than the outside air, as being necessary to prevent the formation of draughts—seeing that the sudden admission of cold air into a warm room is sure to create currents in the process of diffusion; and currents of air should be avoided as much as possible indoors. I therefore arranged the inlets and outlets to each room as shown on the drawing in plan and sectional elevation; A A A A being inlets and B B B B outlets. The direction of the air currents are shown by the arrows.

The air is admitted through an iron grating (which is capable of adjustment) built in the wall at the ground-level outside. The house being built on virgin soil, I was not much concerned about the possibility of ground air entering; but in some localities in London, and other large towns too, ground air is perhaps not very desirable to admit into our houses, and is best to be avoided, which can be done by covering the whole area on which the house stands, and a margin of 5 feet on all sides, with a foot depth of concrete. The air is admitted by the grating; and it rises up the centre of the wall by a brick space being left out, so as to form a conduit 9 in. by $4\frac{1}{2}$ in.—equal to 40 square inches in area—and enters the rooms at 6 inches below the ceiling, through an iron ventilator capable of regulation by means of a flap-valve, which is usually set at an angle of 45° , in order to give the entering air an upward direction to sweep across the ceiling to the outlet-flue. The air entering by this inlet is warmed by absorbing heat from the walls whilst flowing upwards; and as a rule it takes up 14° to 18° of heat before passing into the room. In the winter, when the temperature of the room is about 58° to 60° Fahr., and the outside air 30° or 32° Fahr., and with one-tenth of an inch draught in the inlet conduit, the air which enters is warmed to about 46° to 48° Fahr., and mixing at once with the heated air of the rooms, does not fall, but slowly travels across the ceiling, over the gas-lights, to the outlet-flue, which is situated in the centre of the end wall of the room above the mantelpiece, and between the two smoke flues. An ornamental brass grating is all that is seen in the room; and this communicates with the air-flue, which is 6 in. by $6\frac{1}{2}$ in.—equal to 39 square inches in area, and generally has a draught of $1\frac{1}{2}$ tenths of an inch; but 2 to $2\frac{1}{2}$ tenths in windy days. There is therefore always a constant suction at any time of the day or night. If the flame of a lighted taper is held up within $\frac{1}{2}$ inch of this grating, it is pulled through it with sufficient force to extinguish it. The heated and vitiated air escapes through it at a temperature of 62° to 65° Fahr. This outlet air escape-flue is formed between the two other flues, and is 6 inches wide by $18\frac{1}{2}$ inches long, divided in the centre by a continuous slate partition; thus making two hot air escape-flues 6 in. by $6\frac{1}{2}$ in.—one serving the lower room, and the other one the bedroom above, where there is an adjustable ornamental ventilator fixed in the centre of the apartment over the mantelpiece, 6 inches below the level of the ceiling, and where there is generally a draught of one-tenth of an inch. The air entering by the doors and the windows, no special provision is necessary for the smaller

quantity of air required; the constant pull of one-tenth at the ventilator being all that is needed to keep the air of the bedrooms always fresh. By the hot-air flue being built up with and between the two smoke-flues, the heat of these flues from the lower fires creates a draught independently of the difference in height of the inlet and outlets; but it also answers well in the summer time when there are no fires in the grates, and keeps the rooms constantly replenished with fresh air by removing the heated vitiated air and products of combustion from the gas-lights.

I have on several occasions tested the inflow of air and the exit of heated air, and also the temperature of the rooms; and I have invariably found that I have succeeded in solving the problem I started with. In one room lighted by a 5 feet Sugg's "Cromartie" recuperative burner, I found in the winter time, while the thermometer outside stood at 32° Fahr., the air entering the room was 48° Fahr. At 6 inches above the "Cromartie" burner, the temperature was 72° Fahr.; 3 feet from it, and 3 feet from the outlet, 62° Fahr.; at the exit flue, 12 inches below the ceiling-level, 60° Fahr.; at 4 feet above the floor-level in the centre of the room, 58° Fahr.; and at 1 foot from the floor-level 55° Fahr.—or only a difference of 5° between the floor and ceiling levels. In another room, lighted by four of Sugg's silent "Christiania" burners, on brackets on the walls, the air entering on the north side of the room was 30° Fahr.; coming into the room, it was 42° Fahr.; over the gas-bracket, 1 foot from the ceiling, and 3 feet directly above the burners, it was 88° Fahr.; in the centre of the room, 1 foot from the ceiling, it was 65° Fahr.; at the hot-air exit, 6 inches from the ceiling, 72° Fahr.; at 4 feet from the floor in the centre of the room, 61° Fahr.; and 1 foot from the floor, 58° Fahr.—showing only a difference of 7° between the floor and ceiling levels. This, I think, proves conclusively that the ventilation of these rooms is very efficient; and that the heated and vitiated air was being quickly taken away from the rooms, and as rapidly replaced with fresh air from the outside. As all the fire-places in the rooms are fitted with Barnard, Bishop, and Barnard's (fire-tile, slow combustion, solid bottom) grates, no special means for supplying air to the fires was provided, as these grates require but a small amount of air. Especially when arranged to burn the fuel downwards, without producing smoke, the minimum of air only is required. Had the old form of grate been used, it would have been necessary to provide for a supply of air to ensure proper combustion, something after the plan suggested by Mr. Sugg, in a paper he read before the Institute a few years ago, when the air was delivered from the outside under the raised fender, through perforations made in the hearth, so as not to depend upon any haphazard supply by doors or windows, or supposed transpiration through the walls of the rooms. With the class of grates mentioned, no special air supply appears to be essential, whether burning all coal or half coal and half broken coke, as this method of slow combustion warms the rooms quite as effectually as, if not more so than when the flame of a coal fire goes roaring up the chimney, carrying half the heat with it, and taxing to the utmost limit the air supply from under doors, &c., and producing, by the rush of cold air across the floor to satisfy the blazing fire, the discomfort of cold feet.

This mode of ventilating houses is an easy matter when one has a new house to build; but the question to be considered is, How is it to be applied to gas-lighted rooms in existing houses, so as to obtain like results in the matter of

keeping down the temperature and the renewal of the air by the removal of the heated and vitiated air, and without injuring the building? There may be a little trouble; but I do not think the difficulties are insurmountable. If I had such a thing to do—and I wish some one would give me the opportunity of carrying it out—I would proceed very much on the lines I have indicated. I would arrange an iron, zinc, or thin wooden pipe—say, square in section—in the corner of a room, taking air from the outside at or near the ground-level, and delivering it six inches below the ceiling. Another similar pipe would be fitted in the opposite corner of the room, or close against the side of the projecting chimney breast, having its opening at the ceiling-level. It would run up through the room above; and would be allowed to project a foot or two through the bed-room ceiling into the space below the roof. The heated impure air would then soon find its way outside. There would be a constant pull, and no danger of down draught; and the expense could not be very great. The tubes and opening in the ceiling might have some amount of ornamentation, if thought necessary; but probably, in this æsthetical age, a square pipe might be admired, and not thought plain. However, I could not advise the pipes being let into the walls; for this would cut the walls too much, and very likely endanger their stability. As an alternative means of carrying out this idea, an angle of the room might be utilized by fitting a pine board 11 inches wide into it, enclosing an area of about 40 square inches, which could take its supply of air from the cellar, or below the floor, with an air-brick in the outside wall. For the outlet, the angle formed by the chimney and the wall of the bedroom could, without much disfigurement of the room, be made use of by being enclosed with a $\frac{1}{2}$ -inch by 11-inch pine board painted, stained, or papered, like the rest of the room. If this plan could be carried out—and I do not see where any difficulty arises—I have not the least fear but that the results obtained in the case alluded to would follow; and the difference between the temperature at 1 foot from the ceiling-level and 1 foot from the floor-level in any room so ventilated would never be more than 10°.

For those who will not, or do not see their way to adopt this arrangement, there are many improved forms of ventilating-lamps; indeed, there are so many now, that they are too numerous to mention in this paper. A few weeks ago Mr. Vivian B. Lewes, of the Royal Naval College, gave a lecture on this subject of ventilating gas-lighted rooms; and he described the way in which the Wenham lamp can be utilized for the purpose in large or small rooms. For the last three years, the large rental-office of the South Metropolitan Gas Company, Old Kent Road, has been lighted and ventilated by this means. There are ten of the large sized lamps; and the three centre ones have ventilating shafts conveying away the heated and vitiated air through slate flues above the ceiling, and into the nearest chimney. They answer very well, and give little or no trouble. Mr. Sugg has adapted his inverted burner lamp for the purposes of ventilation by applying them, in a very neat and admirable manner, to brackets on the wall, by which the products are ejected outside the buildings. He is also bringing out the Methven system of supplying a separate current of air—previously deprived of its moisture—to the purposes of ventilation, in connection with his lamp; the air being fed to the lamp under a slight pressure, and the products conveyed to the outside of the room, or to the nearest chimney. All or any of these regenerative

lamps lend themselves readily as a means of ventilation, carrying away not only their own products of combustion, but also the heated and contaminated products of respiration of crowded rooms, the air of which soon becomes poisonous, if lighted in any other manner, without some very efficient method of ventilation. As a recent writer reporting upon the lighting of rooms by means of electricity says: "Glow lamps do not modify the atmosphere and produce less heat, but also at the same time have less ventilating power; and ill-ventilated rooms, with glow lamps and persons in them, become poisonous after a time. Though the composition of anthroptoxin is not yet accurately known, there can be no doubt now as to its existence." This anthroptoxin, it appears, is a deadly poison, and kills quickly when given to animals. It is procured by collecting the condensed products of respiration from crowded rooms, which are badly ventilated, and lighted by any means which do not assist in ventilation. It is seen condensing, and can be collected from the cold glass window panes of such rooms. Whenever this moisture is seen, it is a sure sign of imperfect ventilation; and by opening the windows it disappears.

In conclusion, I trust I have succeeded in showing how ventilation may be made easy, and at little cost; always bearing in mind that the inflowing fresh air should be warmed as near as can be to within 10° or 15° of the temperature of the room. Then there will not be any discomfort to those occupying the rooms; and always a certainty that there will be a steady inflow of pure fresh air, replacing that taken out of the apartment. Our homes may thus be rendered more healthy, comfortable, and enjoyable in the long dark evenings of winter.

The PRESIDENT said he believed the ventilation of dwelling-houses was less understood in England than anywhere else; for we were a long way behind most other countries in this respect. It was a difficult matter to deal with; but Mr. Somerville had treated it in a very exhaustive way. What he recommended appeared satisfactory, if it would be successful. There was one point, however, which rather disagreed with his experience, for he understood Mr. Somerville to advocate the use of Bunsen or atmospheric burners for heating; whilst his (the President's) experience had been that such burners were far more liable to create an unpleasant smell than were ordinary gas-burners.

[It was decided to discuss this and Mr. Leeds's paper (to appear next week) together.]

Essays, Commentaries, and Reviews.

GAS AND WATER COMPANIES IN THE STOCK MARKET.

(FOR STOCK AND SHARE LIST, see p. 84.)

DURING the past week business on the Stock Exchange has been somewhat restricted; but the markets have not dropped. On the contrary, favoured by the continued promise of peace on the Continent, the tendency has been towards better prices generally; and but for some access of stringency in the Money Market, they might have gone higher. The upward movement is fairly well marked in the Gas and Water Departments, though the extent of business done has been decidedly limited. In the former category, the most noticeable feature is the continued improvement in Gaslight "A," which steadily advanced, until on Saturday it was marked at 255½. South Metropolitan "B" has been repeatedly done at 244—the top price; but the quotation is left unchanged. The "A" has not been dealt in at all. One transaction in the old stock, at 267, was all the business in Commercial. Imperial Continental has been dealt in every day, at about level figures. Continental Union and European are rather better; and the debentures of Australian and Buenos Ayres are fractionally higher, on *ex div.* changes. There has been very little doing in the Metropolitan Water Companies; and the only variations are favourable—being a rise of 2 in Lambeth 7½ per cent. and in Southwark ordinary. The daily operations were: Quiet business in Gas on Monday, at fair prices, but without any advance. Two transactions in Kent comprised the business done in Water. Tuesday's business in Gas was largely in debentures, which are still in demand. Upon reference below to the comparative table of prices now and six months ago, it will be noted how the secured issues of Gas undertakings have advanced in price. Wednesday was much quieter. Prices generally were very good; and Gaslight "A" rose 1. Water was almost neglected. Much of Thursday's Gas business was in the debentures of the two Australian Companies, which stand in good estimation. Gaslight "A" rose 1 more, and European improved ½. There was nothing done in Water. Friday was a quiet day in both Gas and Water, and quotations did not move. Saturday was more active than usual, and prices rose. Buyers of Gaslight "A" were 1 higher; and Continental Union advanced. Water was more dealt in; and Lambeth 7½ per cents. and Southwark ordinary

improved 2 each. [ERRATUM: In line 17, last week, for "bring" read "buy."]

We append a comparative table of the quotations of Gas and Water stocks as on the 1st of January last and on the 30th of June. In regard to Gas Undertakings, the most noticeable feature is that, while the open stocks have in many instances failed to maintain their position, the debenture and preferred issues have made considerable advances—a movement which was largely stimulated by the demand for first-class securities created by the conversion of the National Debt. Some considerable improvements have been achieved by the Water Companies; the recovery of New River being the most conspicuous.

COAL FORMATION.—As a contribution to the study of the formation of coal, M. Spring (in a recent number of the *Bulletin de la Société Chimique de Paris*) deals with the proportion of carbon and hydrogen contained in coal-schists. He maintains that the formation and preservation of a coal rich in gas can only have occurred when it was sufficiently protected against atmospheric agencies. The many varieties of coal owe their origin probably rather to the unequal manner in which they have been protected against slow combustion, than to a difference in the kinds of vegetation from which they are derived. Even in our epoch the fattest coals give the most abundant escapes of "fire-damp;" and the presence of this gas under high pressure is certain evidence of the impermeability of the rocks in which this coal has been shut up.

THE ELECTRIC LIGHTING SCHEME FOR BIRMINGHAM.—The Town Clerk of Birmingham has received formal notice from the solicitors of Messrs. Chamberlain and Hookham of the intention of the latter gentlemen to apply to the Board of Trade during the present year for a Provisional Order to authorize them to supply electricity for public and private purposes within the municipal area. The present intention of the promoters is to embrace an area comprising New Street, Colmore Row, Bull Street, and High Street; the current being supplied from Messrs. Chamberlain and Hookham's works in Bartholomew Street. If applications are received for the electric light from persons outside this radius, the area will be extended. The system to be used will, it is stated, supply a continuous current of electricity; and at the central station there will always be a large storage force in reserve, so as minimize risk of a failure of the light.

ELECTRIC LIGHTING MEMORANDA.

REVIVAL OF INTEREST IN PROVISIONAL ORDERS FOR ELECTRIC LIGHTING—THE GROSVENOR GALLERY COMPANY AND THEIR STOKERS—THE MAXIMUM EFFICIENCY OF ELECTRIC LAMPS—THE AFFAIRS OF THE PILSEN-JOEL COMPANY—AN AMERICAN ADVERTISEMENT OF THE BOSTON EDISON COMPANY.

It is impossible to say whether the movement is meant seriously or not; but it is a fact that notices of intended applications for Provisional Orders under the Amended Electric Lighting Act are beginning to fly about the ears of various local authorities in different parts of the country. The Metropolitan Board of Works have received intimations of this nature from three parties, only one of whom—the South Metropolitan Electric Supply Company, Limited—is known by name to us. The two others are styled the London Electric Supply Corporation, Limited, and the Westminster Electric Supply Corporation, Limited. The similarity between the names of these two concerns is to be noted, as it is probably a sign of other relationship. The Alliance and Dublin Consumers' Gas Company have served a notice upon the Dublin Corporation of their intention to apply for a Provisional Order authorizing them to supply electricity within the municipal boundaries of the city of Dublin. A conference has been arranged for in London, at which representatives of the Corporation were to meet the representatives of the Gas Company, with a view to discussing the subject. No intelligence of the result of this meeting has yet been made public. Something has been heard also of a proposed statutory electric lighting experiment at Nottingham. It is quite possible that the passing of the Electric Lighting Act Amendment Act may give an impetus to speculation in this direction; but local authorities, having got over the violent agitations into which they were thrown by the swarms of similar notices issued by electrical speculators in 1883, are not likely to be seriously disturbed thereby. The issue of notices may mean business now, although it did not in 1883; but time will show.

The electrical press continues to notice the tempest in the Grosvenor Gallery teapot, to which we have already referred in this portion of the JOURNAL. It now appears, on the showing of the stokers, that they did not, as alleged, strike work and plunge the district into darkness because they were asked to eat cold beef when they expected hot meat. There seems to have been some unpleasantness between several of the men employed at the station and their superiors; but it was nothing more than occasionally happens in the best regulated factories, and is now declared to have had nothing to do with the hitch in the Grosvenor Company's lighting. What was the actual cause of the breakdown in question is now uncertain; but it is the opinion of the *Electrical Review* that "the stokers have been made the scapegoat of one of the little bangles, which, unfortunately are neither few nor far between at this West-End central station." It will be very funny if the conductors of electric lighting stations, whenever these become general, follow the fashion set by the Grosvenor Gallery people, of inventing comic explanations of their difficulties. The cold meat excuse can hardly be made to serve twice. Next time we may hear that the machinery had to be stopped because the man who attends the dynamos went out to get his hair cut. There is plenty of scope for the imagination in this direction.

Mr. John W. Howell read a paper on the maximum efficiency of incandescent electric lamps before the last meeting of the American Institute of Electrical Engineers, the object of which was to set forth the principles upon which these lamps can be worked to the best advantage. It is easy to perceive that, when the cost of current is high and that of lamps low—especially when in the latter case cheapness is combined with good lasting quality—it is desirable to work the lamps at a high incandescence. On the other hand, if lamps are dear and poor, and current is cheap, high incandescence is not advantageous; but economy is to be found in sparing the lamps at the expense of a little more current. There is, however, a limit at which the cost of lamps must be made to follow the cost of current; and accordingly Mr. Howell lays it down that the cost of lamps should never vary widely from 15 per cent. of the total working expenses of an electric light station. It is, therefore, comparatively easy to ascertain, when the accounts of such stations are published, if they are being worked at the maximum efficiency, since all that is necessary is to deduct from the gross expenditure on revenue account the bills for new lamps; and if these do not amount to about 15 per cent. of the whole, the station is being mismanaged somehow. Dr. J. A. Fleming allowed in 1885 that the lamp charge might be 17.4 per cent. of the whole working expense of a station; but matters appear to have altered in this respect, at least with regard to American lamps.

The Pilsen-Joel and General Electric Lighting Company held an extraordinary general meeting recently, at which the Chairman made a long statement explanatory of the position of the concern. In March last it was recognized that the condition of the Company was desperate; and the Directors accordingly proposed that a call of 5s. per share should be made for the purpose of carrying on the business, at the same time that the capital was to be reduced with a view to the possibility of declaring a dividend. The shareholders, on being appealed to, were disinclined to advance any more money; and, litigation being threatened, the Directors were compelled to make a small call, and also to take steps for disposing of the business of the Company. The course finally adopted was to arrange for the disposal of the concern to a syndicate in which Messrs. Woodhouse and Rawson appear to be interested; and it was this arrangement that was submitted to the proprietors at the recent meeting. The proposal did not satisfy the meeting; and in the end a resolution was carried which practically directed

the Board to reconsider the matter, and joined with them several prominent shareholders in a consultative capacity. It does not look as though the unfortunate Pilsen-Joel Company, any more than the Maxim-Weston concern, is destined to survive into the good time which, thanks to Parliament, is supposed to be dawning upon electricians in general.

Advertisement is tolerably rampant in the United Kingdom, but it is nothing here to what it is in the States. Read for example what the *Daily Graphic* has to say of the management of the Boston Edison Electric Lighting Company. "It takes a bright, quick, active, and pushing man to do what Samuel Insell, Superintendent of the Edison Machine-Works at Schenectady, did in Boston the other day. There was a big fire at the Hub of the Universe, and the station of the Edison Illuminating Company was swept away by the flames. Darkness hovered over the places where from 8000 to 10,000 electric lights had kept bright as day. Mr. Insell happened to be in the city, and he sat down with a telegraph operator while the wires were singing and warm between Boston and Schenectady. It needed quick work; and the work was done. From the Schenectady factory the necessary machinery and appliances were run out and sped on their way to Boston. Then Mr. Insell met them, and, with a swing and energy that made conservative old Boston burn, he put the plant in place; and next night the city lay down to rest in all the glory and radiance of the new-made light." Where be your *Daily Telegraph* writers now? If this is not "graphic" writing, where can such be found? A tame English reporter would have been contented to write that the plant of the electric lighting factory in Boston having been destroyed by fire, fresh plant was telegraphed for, and and set to work by the next night. Such is evidently not the spirit in which an American reporter understands his opportunities. One can feel the slow music with which the monologue description of the great city enveloped in darkness—for the want of a few thousand electric lamps—should be put upon the stage. Then Mr. Insell appears in the character of the Spirit of Light (clarions and drums); and the city "lies down to rest" in artificial daylight once more. Why the city wanted the glorious light to go to bed by must remain a mystery. Surely a tallow candle would have served for that purpose? However, it is a fine bit of writing, and one is tempted to ask of the subject of it whether it cost him much.

THE GLASGOW INTERNATIONAL EXHIBITION.

SIXTH ARTICLE.

IN accordance with the intimation given a fortnight ago, we now proceed to make some remarks regarding the gas cooking and heating appliances in use in and about the Glasgow Exhibition; dealing first with the "installation" in the extensive kitchen connected with the Bishop's Castle Refreshment Rooms. In this kitchen Messrs. R. and A. Main have fitted up two large "Kilburn" gas-ranges, which are together capable of roasting as much as 600 lbs. of meat at one time. Besides this, these ranges are fitted with seventeen powerful boiling-rings on the top. Near by, there is a large double griller, which is capable of grilling 40 steaks or chops at one time. It is divided into two compartments to work together or separately, as may be required. The top of the griller is fitted up as a cutting or carving table. There is also a large carving table which contains recesses underneath for joints, &c., and a hot closet for warming plates. This carving-table, which is 17 feet in length, stands in the centre of the kitchen, and is fitted complete with copper gravy dishes at the back. The hot closet is provided with four sliding-doors, and is capable of heating a great number of plates at one time. Alongside the carving-table there is a large hot-plate with hot closet, which is used for keeping and serving hot pastry, &c.

A special feature of the Bishop's Castle kitchen is Messrs. Main's new baking oven. It is 3 ft. 8 in. square, and is used for baking the fancy tea bread, light pastry, &c. We ought to remark in reference to this oven that it was specially designed and constructed by Messrs. Main for the Glasgow Exhibition. For soups there is a large stock-pot, which has a powerful gas-heater underneath. Its capacity is about fifty gallons. For cooking potatoes, Messrs. Main have made a large steamer which is heated by gas. In it there are provided six oval steaming dishes, each of which is capable of cooking two stone of potatoes at one time—the total capacity being 1½ cwt. of potatoes. For boiling large quantities of vegetables, hams, fish, &c., and for doing general work, there have been fitted up three gas-heated boilers, all containing wire cages and drainers. Then, again, for ordinary boiling work, there is a large boiling-table, having spaces underneath for drying plates, &c. The hot water required is supplied by one of Foulis's patent automatic circulating water-heaters, and is drawn from large copper tubes into the various sinks for scullery purposes. For making tea and coffee, there is a quantity of miscellaneous apparatus, all of which is heated by gas. The kitchen is very commodious; and it is probable that this is the first instance in which cooking has been done on such an extensive scale entirely by the use of gas as the heating agent. The whole of the apparatus has given the most satisfactory results, notwithstanding the severe test to which it has been put. The contractors for the refreshments in the Bishop's Castle Dining and Tea Rooms, deserve great credit for their enterprise in resolving to carry on the work of such a large kitchen by the exclusive use of a gas "installation" for cooking and heating; and Messrs. Main, to whom the work of designing and fitting up the "installation" was entrusted, also deserve a meed of praise, as they have most ably demonstrated the advantages of using gas as the heating agent

under somewhat peculiar circumstances. In view of the forthcoming annual meeting of the North British Association of Gas Managers in Glasgow, we would suggest the desirability of provision being made for the members inspecting the arrangements of this kitchen on the occasion of their visit to the exhibition. They would certainly be much interested. It may be mentioned that the cost of the gas consumed in this kitchen during the season is likely to amount to £700 or £800.

What are known as the Working-Men's Dining-Rooms, situated at the north-west corner of the Machinery Court, are also worked on the same system as the kitchen just passed under notice. The kitchen is likewise furnished with one of Messrs. Main's large "Kilburn" gas-ranges, with boilers on the top. The installation in this case likewise embraces two of the same firm's "Universal Domestic" gas-cookers, No. 5; and there is, in addition, a large double grill and carving table similar to that supplied to the Bishop's Castle kitchen. In the tea-rooms fitted up close by the Women's Industry Section of the Exhibition, and worked by the Committee of the Glasgow School of Cookery, gas is also used as the heating agent. There are two large hot-closets for infusing tea; and each of them has a baking-plate on the top. There are, in addition, two baking-plates for fancy tea bread, &c. The other appliances include a "Foulis" hot-water circulating apparatus and two boilers, which are heated by gas. This installation, like the other two just dealt with, was fitted up by Messrs. Main. The Bodega bar and luncheon department has been furnished by the same firm with one of Foulis's automatic water-heaters (to which there is attached a 50-gallon copper tank), and a double grill and hot closet, with boiling-burners on the tops. At Messrs. Gray, Dunn, and Co.'s stand, located in the Machinery Court, one of Messrs. Main's "Universal Domestic" cookers is in use to illustrate the process of biscuit-baking; and at adjacent stand, Messrs. R. and A. Scott, Limited, of Glasgow, have in constant use two large hot-plates, supplied for the same firm, for baking the famous Midlothian oat-cakes.

Throughout the exhibition there are heating appliances in use of a miscellaneous character which are nearly all employed in processes that are being illustrated to the visitors. At Messrs. Kirkland's Indian Tea-Rooms, which have now become a prominent feature of the exhibition, a number of Fletcher's boiling-rings are employed for heating water for tea-making and cleaning purposes. At the two kiosks in the grounds, boiling-rings are also in use; and at the Ceylon Tea Company's Refreshment Rooms, also in the grounds, there is in use one of Messrs. Main's hot-plates. The heating operations at the Old Dutch House, where Messrs. Van Houten and Son, dispense their cocoa, one of Fletcher's multitubular burners is employed. In the Machinery Court, there is also a stand where the manufacture of cocoa, chocolate, bon-bons, and other fancy articles is carried on; the grinding-mill being heated by gas. At two adjacent stands, gas is also used in connection with hot-plates, &c., employed in the making of confectionary goods. Messrs. R. and J. Dick's extensive stand for manufacturing gutta-percha goods affords an example of the use of gas-fires for providing the necessary heat which the workmen require in their operations. Mr. S. Wright pursues, at his stand in the Machinery Court, the process of barrel-making by machinery; and one of his important requisites is heat for bending the staves. This is obtained by the use of a group of Bunsen burners. Within the exhibition buildings, there are two stands at which hat-making and hat-dressing operations are carried on, at both of which recourse is had to gas iron-heaters. Ironing appliances and washing-machines in action are also shown, which owe their utility in great measure to the employment of gas for heating.

PRESENTATION TO MR. W. W. MONK, OF BOURNEMOUTH.—On Saturday, the 30th ult., an interesting presentation was made at the Bournemouth Gas and Water Company's works, to Mr. Walter W. Monk, who has occupied the position of Engineer of the Company for the past nine years, and is about to retire from the service, having accepted a position as representative at Melbourne of the firm of Messrs. C. and W. Walker, of Donnington. The testimonial consisted of a purse containing 32 sovereigns, and an album with views of Bournemouth; including the Company's works and a photographic group of the South-West of England District Association of Gas Managers, who assembled at the Winter Gardens, Bournemouth, a few years ago. The title-page of the album bore an illuminated address. The presentation was made by Mr. A. Newton, who said he had been asked on behalf of the *employés* of the Company and a few friends to present to Mr. Monk a small token of their esteem on the occasion of his relinquishing an appointment which he had filled for so long and with so much ability. On leaving Bournemouth, Mr. Monk could take with him their very best wishes for his future health, happiness, and prosperity. Mr. Monk, in returning thanks, said it was a great gratification to him to know that he was so highly esteemed by those among whom he had laboured for a number of years, and whose interest he had always had at heart. He hardly knew how to express his pleasure; for, in addition to the handsome present which they had made to him, they would no doubt be pleased to hear that his Directors had recognized his services in a most generous manner. Having referred to his work at Bournemouth and to his future duties in the Antipodes, he thanked his friends for the good wishes they had expressed, and assured them that he was leaving Bournemouth in no discontented spirit, but with a light heart, and with a bright prospect before him. Mr. Monk's health was then proposed, and very heartily received.

THE VENTILATION OF GAS-LIGHTED ROOMS.

A SUGGESTION.

THE subject of the ventilation of inhabited rooms, taken in conjunction with gas lighting, received merited attention at the recent meetings of both The Gas Institute and the Société Technique du Gaz en France. It formed the principal question submitted for the competitive studies of the members of the French Society, who were stimulated in the task by the offer of a substantial premium of £40 for the best paper. Notwithstanding this inducement, however, only one paper was submitted in competition, and even this was not regarded as worthy of the full prize. The author—M. Charles Pot—was accordingly solaced by an award of half the proffered amount, in order that he might be encouraged to continue his study of the subject, and as a testimony to the interest attached by the Société Technique to the general question. When M. Pot's paper is published (which will probably not be until the volume of the Transactions of the Society is issued), we shall be better enabled to form an opinion respecting its merits than can now be done from the curt synopsis of its scope which has come to hand in the report of the Committee that made the award. From the observation that "the author had not sufficiently investigated the data constituting the basis of his work," although he is credited with having "made intelligent use of well-known rules and formulæ," we are, however, inclined to expect that the paper is likely to turn out a distinctly booky performance, not qualified to advance one's knowledge of the subject to a very appreciable extent. It is only a matter of access to the text-books, and of application during a few evenings of leisure, to put together an "intelligent" paper on ventilation, in which well-known formulæ and old data shall be dressed up in a passingly acceptable fashion. The cause of ventilation will not be advanced in this way, however, but only by new triumphs of practical application in those directions where difficulties appear most insuperable.

Mr. John Somerville's paper at The Gas Institute meeting was somewhat diffuse for reading aloud; but it forms interesting matter for private perusal. Mr. Somerville said a good deal round and about ventilation; but the real purpose of the paper was to describe the dispositions whereby the author has succeeded, as he claims, in ventilating a newly-built dwelling-house. It is with reference to this point that the paper must be judged. The author's description of, and reflections upon other branches of his subject are comparatively unimportant. If, as he contends, he has ventilated a dwelling-house by natural means so perfectly that in rooms lighted by open gas-burners there is only a difference of 7° between the temperatures taken at distances of 1 foot from the floor and 1 foot from the ceiling, he has done well; and the paper describing the means whereby such a remarkable result has been obtained must be regarded as a valuable addition to the Transactions of The Gas Institute. In using the conjunction with which the last sentence begins, we do not mean to cast any doubt upon Mr. Somerville's results, but only to indicate their extreme importance. Such a record of the effect of natural ventilation is quite unprecedented, and one cannot help wishing that some independent authority in this matter of ventilation would look into them, and institute a series of check observations. The issue is quite important enough to warrant this inquiry.

It will be noticed that Mr. Somerville's plan is simplicity itself. He has a modification of the Tobin tube for the admission of air—the modification being of the essence of the design. Air, admitted at the bottom of a rising channel formed in the brick-work of an outer wall, enters the room very near the ceiling; the point of discharge being guarded by an angular flap-valve. On the other side of the room, in the chimney-breast, and also near the ceiling, is an outlet leading into an air-shaft carried up alongside the smoke-flues, and terminating like them in a chimney-pot outside. That is all. With this simple means, the temperature of the upper portion of the apartment is kept low, notwithstanding the free burning of gas for lighting, by the constant flow of fresh air from the inlet to the outlet, which carries away all the products of combustion and respiration.

One would like to be sure, with reference to this very remarkable bit of house ventilation, whether it always works equally well in winter as in summer; whether there is ever any back draught from a reversal of the current in the outlet flue; and what influence the burning of a brisk open fire in the grate has upon the ventilating currents. The latter question is partly answered by Mr. Somerville's own statement that the rooms are warmed by Barnard, Bishop, and Barnard's slow-combustion grates, which probably make a different demand upon the air supply of a room to the old-fashioned "slam-register" in general use. We incline to the opinion that in most cases, whatever the kind of grate used, a special air supply for the fire must be provided if there is not to be occasional trouble with the general ventilating arrangements through reversal of air currents. Atmospheric conditions vary so much that it is almost impossible for any system of ventilation depending upon natural draught to be preserved from occasional disturbance; but, of course, a little difficulty now and again would not weigh very heavily against a high average of success such as is witnessed to by Mr. Somerville's figures. A valuable part of the paper contains the directions of the author for the establishment of a ventilating system like his own in old houses; from which it would appear that the expense of such an improvement could not be very great if undertaken at the usual time of repainting, papering, and "spring-cleaning." We hope to hear that this good idea has been followed by other engineers bent on showing a good example in this

matter. One or two well and cheaply ventilated houses in a town cannot but have a great "missionary" influence.

And now we have a suggestion to offer, which The Gas Institute may or may not think fit to adopt. Some years ago—and the custom may be yet in existence—it was the practice of the Sanitary Institute or the Society of Arts to offer premiums for the best examples of household sanitation, precisely as agricultural societies offer prizes for the best cultivated farms. Why should not the same course be pursued with regard to ventilated and gas-lighted apartments? If it is sometimes advisable to offer premiums for papers upon defined subject, it is certainly reasonable to award prizes for the practice of advice given in papers. What is wanted now in connection with the question of ventilation is not theorizing or the application of formulæ to supposititious examples, but examples of well-ventilated houses. We suggest, therefore, that a special fund should be formed by donations from gas companies and individuals interested in this subject, just as was done for the support of the research work of the Institute, which seems to have come to a sudden stop for the want of a programme. From this fund a prize of (say) £50 should be offered for the best example of a ventilated, gas-lighted house in any part of the kingdom, with £20 as a consolation prize for the second, and £10 for the third. It should be a condition of the competition that the designers of the competing systems should prepare illustrated descriptions of their work and its results, to be read, if so required, at the next ensuing Gas Institute meeting, and in any case to be published in the Transactions of the Institute. The source of every such design should be acknowledged, if not original; and the Committee might be empowered to make any division of the prizes that they deem equitable between the actual author of any design and the competitor who has merely carried it into effect. It should not be the object of the competition to force a misleading appearance of novelty in connection with any application of published principles; and the Committee would not divide a premium unless the indebtedness of the adaptor to the original designer was very obvious. The idea should be to recognize in the fullest degree the successfully ventilated house, without depriving the builder of his reward out of too scrupulous respect for the success of his inspiration. After taking note of what the designers or adaptors of the various systems had to say for themselves, the Prize Committee would make a provisional selection from those submitted to them, to be tested in any required way by independent examiners according to some predetermined standard. The principal elements of such a standard are not difficult to imagine. It should be required, in the first place, that the competitors' own claims and tests should be verifiable upon independent examination. Secondly, the degree to which the requirements laid down by the Committee respecting differences between ceiling and floor temperatures, absence of draughts, proportion of carbonic acid in the contained air of rooms, and so forth, might be fulfilled, should be ascertained by independent testing. Then the questions of cost and facility of application of these systems should be taken into consideration. Speaking generally, preference should be shown for systems which dispense with patented specialties of all kinds. It would not be difficult to procure a couple of practical examiners anywhere in the Kingdom who could be trusted to make a reliable test of any specimen of house ventilation submitted to them, provided that their attention was called in the first place to the points requiring investigation. An architect and a chemist would constitute a good pair of examiners into matters of this kind. A couple of years, and the expenditure, in premiums and expenses, of (say) £100, would go far to establish something like a standard of house ventilation, the observance of which could not fail to be beneficial to the community, and particularly to that portion of it which is directly interested in removing from lighting the stigma of unhealthiness, which is so recklessly thrown by its enemies upon this system of artificial lighting. The suggestion herein is, of course, crude; but perhaps sufficient has been said to prove that something more than the composition and publication of papers on ventilation is needed if that which everybody desires in connection with the subject is to be obtained. House ventilation is no promising field for patented specialties, and it will therefore be left unexploited by those whose interest in the subject is solely commercial. It is for this reason that we advocate the giving to practical efforts in regard to the ventilation of gas-lighted room of some such fillip as the premium contemplated in this article would probably impart. The thing could easily be done if one or two public-spirited engineers would take it in hand.

By the appointment of Mr. W. R. Chester, Manager of the Bradford Road Gas-Works of the Manchester Corporation, in succession to Mr. Lewis T. Wright, Assoc. M. Inst. C.E., as General Manager of the Nottingham Corporation Gas Department, a vacancy is created on the technical staff of the great Lancashire gas undertaking. Mr. Chester went to Manchester about eight years ago from the Vauxhall works of the South Metropolitan Gas Company, where he was assistant to Mr. P. J. Wates; and after being engaged at the new Rochdale Road and other works of the Corporation, he was finally appointed to superintend the Bradford Road station. Mr. Chester's antecedents therefore seem to render him specially suitable to take charge of the important works which Mr. Wright has conducted with so much ability; and there can be no reason to doubt that in his hands they will continue to furnish a very substantial amount of profit to their owners.

Notes.

THE LEBRUN REGENERATIVE GAS-LAMP.

The accompanying illustration represents the external appearance and the internal construction of a gas-lamp of the recuperative type designed by M. Lebrun, and recently described in *La Nature*. It is somewhat similar to the Danishevski lamp in general appearance, owing to the fact that the regenerative fittings are suspended over the flame, and that the necessary draught is obtained by means of a glass chimney. The gas is led into the interior of the globe through the pipe D, which is terminated by a radial burner. Over the burner hangs a closed cylinder C, the lower part of which B is perforated with a great number of small holes, while the upper portion communicates at A with the outer air, by means of a number of radial tubes. The top of the glass globe is closed by a metallic crown, between which and the glass there is a packing of asbestos to make an air-tight joint. There is

a hole in the bottom of the globe, which is opened for lighting the burner, and closed at other times. The working of the lamp is now easily understood. When the burner is lit and the globe closed, the contained air is heated, and escapes by the chimney; the draught thus produced drawing the external air through the tubes A into the cylinder, whence it escapes by the lower holes, and immediately combines with the burning gas, rendering the combustion complete and brilliant. Three patterns of these lamps are constructed, of 4, 9 and 16 Carcel power respectively; the consumption of gas per candle being given as 39, 33, and 32 litres per hour in the different sizes of lamps. The Lebrun lamp is described as burning well, with a white and steady light.

A FLAMELESS CARBON LAMP.

At a recent sitting of the Académie des Sciences, M. Hirn exhibited a flameless lamp. It is commonly known that platinum heated in a stream of hydrogen with atmospheric contact will preserve its incandescence as long as the conditions remain unaltered; and in this lamp of M. Hirn the same phenomenon is produced by carbon instead of platinum. The discovery of the principle of the new lamp was made accidentally. Requiring to extinguish a spirit lamp, and having for this purpose covered the wick with the usual glass extinguisher, M. Hirn noticed that the point of the wick remained in a state of ignition. He thereupon removed the glass cover, and the carbonized cotton remained red for nine hours. Upon this principle an incandescent carbon lamp has been constructed; and although the light emitted from the glowing wick is, of course, insignificant, the phenomenon is interesting, and may lead to renewed attempts to penetrate the mystery of luminosity at low temperatures, which has puzzled mankind ever since the glow-worm was first remarked by a half-savage field naturalist.

THE PROTECTION OF BUILDINGS FROM LIGHTNING.

In the course of a lecture on the "Protection of Buildings from Lightning," delivered by Professor Oliver J. Lodge, F.R.S., before the Society of Arts, he remarked that the complete and certain protection of buildings from this special danger is by no means so easy a matter as the older electricians thought it, especially as it appears since the rise of the modern practice of running lines of metal piping for gas and water inside houses. If any such conductor as a gas-pipe passes out of the building before being thoroughly connected with the walls, it is possible for a spark to pass from something in the interior of the edifice to this conductor whenever a flash strikes the building. In many cases it may be well to rest content with something less than absolute security, and to be satisfied with the probable safeguard of a common galvanized iron rod or rope. For tall and important buildings, isolated chimneys and steeples, and powder magazines, Professor Lodge was reluctant to advocate anything that might be taken as a nostrum, and so conceal the principles involved. He declared his preference for a number of lengths of common telegraph wire; thinking a large number of thin wires preferable to a single thick one. The capacity of such conductors must be in-

creased whenever possible by connecting up large metallic masses, such as lead roofs, &c.; the connection being thorough, and made at many points, to prevent sparks. The earth connection should be deep enough to avoid damage to surface soil, foundations, and gas and water mains. As to the roof, barbed wire should be run all round the eaves and ridges, so as to expose innumerable points; and the highest parts of the building must be specially protected. But Professor Lodge would not run any rods above the highest point of the building, so as to precipitate flashes which might not otherwise occur, in search for a delusive area of protection which has no existence.

A NEW WATERPROOFING LIQUID FOR BRICKWORK.

According to the *Mittheilungen des Bayrischen Gewerbe Museums*, walls of houses and buildings exposed to wet may be satisfactorily treated with a solution of paraffin in heavy coal tar oil. It is reported that a number of experiments on damp walls with this preparation have yielded very good results. Papered walls, which formerly in wet weather showed dampness, gave no traces of damp after the external application of this remedy. The solution is prepared by dissolving, at a moderate heat, one part of paraffin in from two to three parts of coal tar oil. Care must be taken to use sufficient oil, so as to prevent the mixture from becoming sticky after cooling; at the same time it must not be too thin. In order to keep the solution liquid during use, it must be kept in a vessel standing in hot water. A couple of glue pots, one being warmed over the fire while the other is in use, would be a good means of keeping the preparation in good condition while in course of application. If possible, the painting should be done during hot days, when the bricks or stone of the wall are very dry and absorbent. One application is sufficient; and the cost of the preparation is very moderate.

Technical Record.

SOCIÉTÉ TECHNIQUE DU GAZ EN FRANCE.

THE PAPERS AT THE BOULOGNE CONGRESS.

In the general notice of the proceedings at the recent congress of the Société Technique du Gaz en France which appeared in the *JOURNAL* for the 12th ult., a list was given of the papers presented on the occasion. We are now in a position to make our readers acquainted with the nature of the various communications, from the abstracts which have just been published in a special number of the *Journal des Usines à Gaz*.

Dealing first with the prize paper of the year—"The Ventilation of Dwelling-Houses and other Buildings Lighted by Gas"—which has already been briefly referred to, the author (M. Charles Pot) has divided his subject into two parts. In the first, he has examined the general conditions of ventilation—dwelling particularly on the use of high-power recuperative gas-burners; in the second, he has applied to the ventilation of a dwelling-house, a workshop, a school, theatres, and a tenement building, the principles laid down. Having defined the principle of ventilation, the author determines successively the quantities of air consumed and the amounts of heat generated by human beings as well as by various systems of lighting. He then enters in detail into the circumstances of the ventilation of localities illuminated by gas; explaining the action of recuperative lamps, and recapitulating propositions previously laid down by another member of the Society. He cites his own personal experience on this matter; and shows that if the light of one Carcel (say, 9.5 candles) is obtained with the consumption of 33 litres (1.15 cubic feet) of gas in a recuperative burner, as laid down by M. Coindet, it must be reckoned that at the distance of a metre the temperature of each cubic metre of ventilating air is raised, at the expiration of an hour, to the extent of 0.0077°C. per Carcel. The author next gives some results taken from the report of Dr. Renck on the ventilation of the Salle Royale of the Odéon in Munich. In a full room, by the aid of recuperative burners on Grove's system, the temperature did not increase more than from 4° to 5° C.; while the proportion of carbonic acid did not rise beyond 0.186 per cent. The author specifies the conditions under which the withdrawal of the vitiated air, the introduction of fresh air, and the hydration of the air should be effected; and closes the first portion of his paper by quoting from the report of the Commission on Hygiene of 1887 and the works of Dr. Tavignat (1858). Having stated his principles, the author, in the second part of his work, proceeds to apply them in connection with the ventilation of the various places above enumerated. Among the cases studied, the one which deals with the lighting and ventilation of a workshop 1050 square metres in superficial area and 4 metres high, occupied by 20 men, and lighted by 12 recuperative lamps (each of 16-Carcel power, and giving the light of one Carcel with a consumption of 33 litres of gas per hour), and that which has reference to the ventilation of various modern theatres, must be regarded as the most interesting. Such, in its broad outlines, is M. Pot's communication. The number of our French contemporary from which the foregoing particulars are taken contains the criticisms of the Committee of the Société Technique upon the *mémoire*; but it will, perhaps, be more convenient to deal with these in connection with a fuller notice of the paper which we hope to give when the full text has been published.

The first ordinary paper was on "The Most Practical Means of Developing the Consumption of Gas;" the author being M. Melon. He referred at the outset to the system of differential prices which is now in force in Brussels, and which is, he

maintains, making its deplorable consequences felt year by year. The author is a partizan of the system of a sliding scale of charges according to the total annual consumption of gas. He dwelt on the necessity imposed upon gas companies of looking after customers, and facilitating the use of gas by them by offering to lay on a supply on the simplest and least costly conditions. M. Melon alluded to the particulars given by Mr. T. Duxbury, in the course of his address, at the meeting of the Manchester District Institution of Gas Engineers in March last, as published in the *JOURNAL* at the time, and used them as a basis for the discussion of the various reasons adduced against the introduction of gas into apartments. He expressed the opinion that deposits should be abolished when the consumer is prepared to offer an adequate guarantee; that meters and fittings should be let on hire at the very lowest figures; and that accounts should be collected monthly, fortnightly, or even weekly in the case of small consumers. In order to counteract the influence of petroleum and electricity, it would, he thought, be advisable to lay on a supply of gas gratis, on condition that the consumer would undertake, for a certain number of years, to burn only the company's gas, with an annual minimum consumption per burner. This system has been adopted at Lille; and the author submitted to the meeting forms of the various agreements into which a consumer could enter. He closed his interesting paper by remarking that the suppliers of gas were powerless to enforce the adoption of gas in every house; but they could all offer a gratuitous installation on the conditions he had indicated. He assured his colleagues that they had in their own hands the means of rapidly doubling the consumption of gas in all the towns lighted by them.

The next paper was on a similar subject, and dealt with the distribution of gas among the consumers. The author was M. Le Roy; and he took some statistics published in the *Journal des Usines à Gaz* in March last as a model for a case of a gas-works having a *clientèle* composed of ordinary consumers as well as tradesmen and manufacturers. It was, he said, curious to notice that, even in this case, the consumers who burn from 1 to 5 cubic metres per 24 hours represent 94 per cent. of the total number, and 44 per cent. of the entire annual consumption. Suppliers of gas had, he considered, a primary interest in popularizing the use of gas, and in increasing the quantity burned by small consumers who pay the full rate, and whose accounts do not produce a sufficiently large sum to tempt the electricians. The author was of opinion that gratuitous installations, if such were possible, or, at all events, installations at cost price, with deferred payment, and the loan of gas appliances at a reduced rate in view of the possibility of purchase during the first year, were excellent measures to be adopted for increasing the number of consumers. Altogether, the paper contained some instructive statistics.

The two latter communications were discussed together. Mr. H. M'Lauchlan Backler acknowledged the excellence of the principles laid down by the authors; but he thought that in each town the temperament of the consumers ought to be taken into account in selecting the method to be pursued towards them, so as to choose the one that would be most in accordance with the habits of the population. M. Jouanne cited the cases of Lisieux and Cherbourg, where installations of gas—comprising a service-pipe, meter, cooking-stove, and two ordinary burners—at a reduced price had led to a considerable increase in the number of consumers. In one year there was an addition of 600 at Lisieux, and of 1000 at Cherbourg. M. Alavoine considered the minimum consumption indicated by M. Melon (150 cubic metres, or about 5300 cubic feet, per burner) was rather high for many of the provincial towns; and consequently this was a matter that would require study in each case. M. Melon replied that his minimum agreed with the average consumption, and was borne out by the actual price of gas at Lille. M. Cornuault explained the measures adopted by the Marseilles Gas Company. They charged, he said, rentals of 1fr. 25c. and 1fr. 50c. per month for a service-pipe, meter, and some simple gas apparatus at the choice of the consumer. The public appeared to prefer the loan of fittings, &c., without entering into any undertaking as to consumption, to a gratuitous installation with such an undertaking. M. Léon said it would be necessary to distinguish, in the case of installations, between dealing with the landlord and with the tenant of a house. In towns where the population was a floating one, or where the residents removed from one part of the place to another, it would be advisable to deal with the landlord, in order to avoid loss. M. Cornuault cited a case in point in Barcelona, where the meters are fixed by the Company at the expense of the landlords, who let their apartments with the installation of gas. The various meters are located in a cellar; and each lodger has the use of one, but only pays the Company for the gas consumed. To a certain extent this system agrees with that adopted in Paris in reference to the supply of water in houses where there is a service on each of the floors. The landlord is the only person responsible to the Municipality for payment; and he recoups himself out of the rent for the apartments supplied.

The next paper was one bearing upon manufacture; the author—M. Charles Pot—taking as his subject the heating of retorts by means of blocks of compressed breeze, by ordinary breeze, or by coke. The chief points of interest in the communication were the particulars given by M. Pot as to his arrangements for the manufacture of the fuel-blocks. These are not reproduced in the abstract from which our notes are taken.

After this came a paper by M. Jouanne on M. Largeron's system for the suppression of the dip in hydraulic mains, which was described and illustrated in the *JOURNAL* for Jan. 24 last

(p. 150). In the discussion to which this paper gave rise, M. Le Treust questioned the advisability of suppressing the dip, whatever might be the system proposed. He considered it to be dangerous to draw off the gas directly from the retort; and gas engineers would, he said, readily understand the reason, without requiring him to furnish details. M. Jouanne remarked that it was always possible to keep a sufficient water-seal by means of the cup placed between the ascension-pipe and the hydraulic main. By raising this cup, the dip was immediately re-established. M. Le Treust said he had tried to dispense with dips, but had been compelled to abandon the idea owing to the great inconvenience it entailed. The President (M. Ellisson) closed the discussion by pointing out that the Largeron system did not present very great advantages, and might interfere with the manufacturing operations in the event of unskilfulness on the part of the workmen. In gas-works, it was of the very first importance to ensure the regular working of the various portions of the plant; and the most ingeniously contrived appliances should not be employed if they were not at the same time so simple as to allow of their being entrusted to ordinary workmen.

The two succeeding papers dealt with the purification of gas. One was by M. Melon, on the working of a Kirkham washer-scrubber; and the other by M. Alavoine on purification *in situ*. M. Melon's experiments were directed to ascertaining the extent of the absorption of ammonia and carbonic acid by the above-named apparatus. During the period in which the trials were going on, the gas was made exclusively from coal from the north of France. After flowing through a long foul main 30 inches in diameter, and passing an annular condenser, the gas reached the exhausters, and finally entered the washer-scrubber, the capacity of which was 25,000 cubic metres (883,000 cubic feet) per diem, and its speed from three to four revolutions per minute. The daily make of gas ranged from 20,000 down to 8000 cubic metres. Pure water was employed in the apparatus—the quantity introduced per 24 hours naturally varying with the make of gas; and it was arranged that the water in the last chamber should not show any indication on the Beaumé hydrometer. The ammoniacal liquor as it flowed from the apparatus had a strength of from 3° to 5° Beaumé (8 oz. to 13 oz.). In the various experiments the temperature of the water ranged from 46° to 57° Fahr. The temperature of the gas on entering the washer-scrubber ranged from 50° to 68° Fahr. Under normal conditions of work, the apparatus showed the following results:—On entering, the gas contained 0·95 gramme of ammonia per cubic metre; on leaving, 0·5 gramme—showing an absorption of 0·70 gramme. The quantity of carbonic acid in the gas on entering was 2·70 grammes per cubic metre; on leaving, 2·60 grammes—absorption, 0·10 gramme. When ammoniacal liquor was introduced into the first three or four chambers, the quantity of carbonic acid taken out of the gas rose to 0·40 gramme per cubic metre. As the gas was sent out for consumption containing 2·20 grammes of carbonic acid per cubic metre, the quantity taken out by the purifiers was only 0·10 gramme, or just one-fourth of the quantity removed by the Kirkham washer. In all the trials, the importance of the degree of temperature at which the water was put into the apparatus was noticed. The colder the water, the easier the absorption. It must be noted that in this series of trials the make of gas per 24 hours did not exceed 800 cubic metres or only about one-third of the maximum quantity for which the washer was constructed. A curious fact was revealed by the daily analysis of the gas. On several occasions the quantity of carbonic acid contained in the gas as used by the consumers went up suddenly from 2·20 to 2·80 grammes per cubic metre—an increase of 0·60 gramme, or 21·43 per cent. The tests made at the inlet to the apparatus at the same time showed a rise from 2·70 to 3·30 grammes in the quantity of carbonic acid contained in each cubic metre of gas. It was subsequently found that these sudden variations corresponded exactly with the extinction of one or more of the furnaces, during which the charges of coal had been gradually lowered in order to cool the retorts. M. Alavoine's communication gave an account of some observations made in a gas-works where 461,900 cubic metres of gas were purified with about 12 or 13 cubic metres of purifying material and 3 cubic metres of powdered lime, without change. Four-fifths of the material was revived *in situ*.

The remaining papers will be noticed in a subsequent issue.

THE COST OF THE WINDSOR WATER-WORKS ARBITRATION.—The total cost of the proceedings incidental to the transfer of the Windsor and Eton Water-Works to the Windsor Corporation was £3984 15s. 5d.

EDINBURGH AND LEITH GAS COMPANY.—The annual meeting of this Company was held yesterday afternoon. The Directors reported that the net profit on the year's transactions was £26,313. The cost of manufacture had been 16s. 9d. per ton of coal carbonized, compared with 22s. per ton in 1883, before the scheme of reconstruction of the works began. The saving effected by the new works had therefore been 5s. 3d. per ton, or £10,433 on 39,744 tons of coal used during the year. The quality of the gas had been 28·13 candles—being an increase since 1883 of 1·44 candles. The unaccounted-for gas stood at 7·63 per cent. The report was adopted; and it was also agreed to declare a dividend of 10 per cent. Subsequently, the agreement entered into with the Corporations of Edinburgh and Leith, for the transfer of the Company's property, was approved. A vote of thanks was accorded to the Directors for the able manner in which they had conducted the concern.

THE CITY AND GUILDS OF LONDON INSTITUTE LECTURES ON GAS MANUFACTURE.

As already intimated in our columns, a course of four lectures on "Gas Manufacture" will be delivered at the Central Institution of the City and Guilds of London Institute, South Kensington, on the evenings of the 17th, 19th, 23rd, and 24th inst., by Mr. Lewis T. Wright, Assoc. M. Inst., C.E.. The following is a syllabus of the lectures:—

1.—The coals employed in gas manufacture; their composition, properties, and characteristics. The distillation of coal considered as a chemical and mechanical operation; the range of temperature employed. Differences in the composition and properties of the resulting distillation products—viz., gas (with its impurities), coke, tar, &c.—with different coals and distillation temperatures. Distribution of the constituent elements of the coal among the distillation products. Differences in the quality of the gas at various periods of the charge. The extent to which the composition of the distillation products can be controlled by various systems of distillation. Apparatus employed: Retorts and settings; refractory materials; chimneys and flues; retort mouth-pieces; ascension-pipes; hydraulic main and retort-house fittings.

2.—The condensation or cooling of crude coal gas. Various types of condensers. The purification of gas from tarry matter. The removal of ammonia, considered chemically and practically. Various forms of washing apparatus; how far these attain their object. Gas purification by means of ammonia.

3.—The purification of gas by means of oxide of iron and lime. Various systems of gas purification, and their respective efficiency with regard to the three principal impurities—viz., carbonic acid, sulphuretted hydrogen, carbon disulphide. The theoretical considerations that most control economical practice. Gas-purifying vessels. Valves. Gas purification without nuisance. The storage and distribution of coal gas. Governors and gas-mains. Leakage. Service-pipes. Consumers' meters. Gas-burners and gas illumination generally.

4.—The arrangement of gas-works, and the design and cost of plant. The expenses incidental to gas manufacture, and the cost of producing illuminating gas.

MR. BRAY AND THE GAS INSTITUTE.—Last Friday another step was taken in the proceedings instituted by Mr. G. Bray against the Past-President (Mr. C. Gandon), certain members of the Council, and the Secretary (Mr. W. H. Bennett) of The Gas Institute, with the view of testing the legality of the vote taken at the recent meeting of the Institute on the question of his expulsion. The matter was brought before Justice Kay; but on the application of the defendants' Counsel (Mr. Renshaw, Q.C.), it was adjourned till next Friday, to allow time for answering the plaintiff's affidavits.

MR. W. CARR AND THE NOTTINGHAM APPOINTMENT.—Referring to this matter last Saturday, the *Halifax Courier* said:—"Mr. W. Carr, Manager of the Halifax Corporation Gas-Works, was one of the candidates for the post of Manager and Engineer of the Nottingham Corporation Gas-Works. Out of the total number of applicants, Mr. Carr was one of the two who were finally selected to go before the Gas-Works Committee of that town, on Thursday; the other one being Mr. Chester, of Manchester. Mr. Chester was ultimately selected, but Mr. Carr was informed that he would have had the appointment but for the allegations which were being made against the Halifax Gas-Works Department, and which were as yet, of course, *sub judice*. The Chairman expressed great regret that the Committee were not able, because of this, to recommend Mr. Carr to the Council; he being, in their opinion, the most eligible candidate. A resolution to this effect was placed on the Committee's minutes. The salary offered is £600 a year."

PRESENTATION TO MR. C. W. FOLKARD.—Last Thursday evening a number of the *employees* of the Brentford Gas Company assembled in the band-room attached to the works, for the purpose of taking leave of Mr. C. W. Folkard, the Assistant-Engineer (who, having been appointed Engineer and Manager of the Bournemouth Gas and Water Company, is retiring from the service of the Brentford Company), and of presenting him with a testimonial, consisting of a very handsome secretaire and purse, as a token of their respect and esteem. The Engineer and Manager of the Company (Mr. F. Morris) presided; and in a few well-chosen words, said they had met for the purpose of saying "Good-bye" to Mr. Folkard, and of wishing him success in his new home. He had also the pleasure of presenting him with the testimonial they saw before them, which had been subscribed for by his friends, brother officers, and the men employed on the works. Whilst congratulating Mr. Folkard on his appointment, he, personally, was very sorry to lose him; as the zeal and ability shown by him in the performance of his duties had relieved him (Mr. Morris) of a great deal of responsibility. Having specially referred to Mr. Folkard's work at Brentford, he concluded by saying he was sure he expressed the views of all present in most cordially wishing Mr. Folkard success in his new career, which he trusted would be as prosperous at Bournemouth as it had been at Brentford. Mr. Folkard, in reply, expressed his warmest thanks for the very handsome and useful gifts, which would, he said, be a lasting memento of his connection with the Brentford Gas Company. He assured those present that the eight years he had spent with them were among the happiest of his life; mainly due, he believed, to the uniform kindness of Mr. Morris and his brother officers. He also thanked them very much for their kind wishes for his future success. The proceedings, which were very harmonious, were brought to a close with a vote of thanks to Mr. Morris for presiding.

THE EXPLOSION AT THE MONTREAL GAS-WORKS.

In the JOURNAL for May 29 last (p. 964) we gave a brief account, obtained from press telegrams, of a serious explosion which occurred on the previous Saturday at the Hochelaga works of the Montreal Gas Company; resulting in the destruction of a large gasholder and the sacrifice of several lives. No additional particulars reached us till the arrival of the *American Gaslight Journal* for the 16th ult., which contained an article describing how the disaster occurred, and giving a summary of the proceedings at the Coroner's investigation. Through the courtesy of the Secretary and Manager of the Company (Mr. J. F. Scriver) our contemporary was able to give illustrations, taken from photographs,

of the wrecked holder; and from these the accompanying engravings have been prepared. The article was as follows:—

The engravings afford vivid pictures of the wreck of the double-lift holder, which was about to be finished by the Montreal Gas Company for the relief of their Elm Street station. The outer lift was 120 ft. 6 in.; the inner lift, 119 ft. 6 in.; each lift being 24 ft. 6 in. The entire structure was enclosed in a 16-sided brick building, covered in by an iron and steel roof. After many months of preparation, arrangements were being made on May 26 to test the holder. On this date water was turned into the tank. When the water had risen to a height of 10 feet, it was discovered that a serious leak existed somewhere in the masonry. The pumps

THE WRECKED HOLDER AT THE MONTREAL GAS-WORKS.

were started, and when three feet of water had been drawn off, the weak spot was located (the tank, however, was completely emptied) in one section of the wall. The puddled cone-shaped bottom was found to be perfectly tight. When the defect had been remedied, the operation of filling was again commenced, but had not proceeded to any extent before the Company's Engineer, in order to satisfy himself thoroughly as to the solidity of the bottom, ordered a stoppage of the flow, and instructed one of the fitters to remove two of the manhole covers, prior to his (the Engineer's) descent to make the desired investigation. The fitter (a known and tried hand of the Company, who had been in their service for twelve years), for reasons which will always remain undiscovered, evidently determined to make an inspection on his own account. Having removed only one of the manhole covers, he procured a ladder and an open lantern, and entered the holder. The terrible result of his fatuous course was the destruction of the inner lift of the vessel, the walls

and roof of the structure enclosing it, and the mangling to death of himself and four others, while five of his remaining fellows only escaped death to bear through their lives the scars of many wounds. No gas had as yet been turned into the holder, although all the connections had been made. The inlet valve (a 20-inch) was perfectly tight; while the outlet (a 24-inch) leaked slightly; but the pipes were said to be water sealed. Beyond a doubt the fitter and his comrades, including the Engineer, had no fear that gas had escaped into the holder; but such assurance is not to be allowed to go for anything in an attempt to extenuate the act of the unfortunate who with his life—and, worse still, that of others—paid the penalty of his rashness. We presume it is not necessary for us to here attempt to give an explanation of how the gas might have escaped into the destroyed vessel, for every engineer who reads these lines will form his own theory; and we have an idea that no great difference will exist in the nature of the opinion so formed.

The entire structure, from foundation to roof, stands the Company, in round figures, an expenditure of \$80,000; and experts who have since roughly examined the wreck say the net loss to the Company will not exceed 40 per cent. of this sum. The foundation and tank masonry, together with the outer lift, are practically intact, and a considerable portion of the inner lift and roof can be used again. In any event, we may add that, quite in keeping with the energy characteristic of the Company, they are already at work on the renewal of the destroyed structure.

The testimony taken at the coroner's inquest seems rather to add to the mystery of the affair than to take from it—that is, in respect to determining how the gas escaped into the holder. The

affirmation of R. Colquhoun, who was one of those seriously injured, and whose testimony was taken while he was writhing on his bed, is so graphic that we herewith present a summary of it. He testified that he had been in the employ of the Company for 17 years, and on the morning of the disaster was in the second gallery of the holder house, painting some of the heavy timbers in the gallery chambers. He saw Joseph Angell remove the manhole cover, being assisted in the operation by John Angell and S. M'Afee. When the cover had been removed, Angell ordered M'Afee to bring a lantern, and, this duty performed, M'Afee and John Angell lugged a ladder to, and placed it in the manhole. Angell then tied a cord on the lantern, placed himself on the top rung of the ladder

THE WRECKED HOLDER AT THE MONTREAL GAS-WORKS

and dangled the lantern down into the tank. Then, to use Colquhoun's own words: "When I saw him lowering the lantern I put both my hands to my face, for I had been long enough in a gas-works to know what to expect. The crash followed instantly; and the next thing that I remembered was finding myself on top of the tank, bricks and iron being heaped up all around me. Colquhoun's testimony would go to show that he at least of those who were on the premises at the time thought there was gas in the tank. Indeed, his action in putting both hands to his face is proof positive of his suspicion. The jury, after reviewing the evidence, returned the following verdict:—"We find that deceased came to their deaths from injuries received as the result of an explosion of a mixture of coal gas and air contained in a gasholder on the grounds and in a building the property of the Montreal New City Gas Company; and that the said explosion was caused by the introduction of a lighted lamp in the said gasholder by the late Joseph Angell, an *employé* of the said Gas Company, and one of the victims of the explosion. We further find that the said Joseph

Angell, in introducing the light into the gasholder, acted through ignorance and imprudence, and not from malice or with intent to do hurt or injury."

STEEL WATER-MAINS.—The Engineer of the Dundee Water Commissioners (Mr. J. Watson, M. Inst. C. E.) reports that since January last the supply of water to Newport has been given by gravitation, *via* the Tay Bridge. The steel main, 9 inches in diameter, laid along the new Tay Bridge a distance of two miles, was completed during the early part of the year, and was for some months subjected to hydrostatic pressure, and has been in constant work since January. Notwithstanding the constantly recurring vibration by train traffic, neither during testing nor in working has a single accident taken place in the metal or construction of the pipe; and repairs have been confined to some trifling leakages at the lead and expansion joints—principally the latter. On the whole, this work is proving very satisfactory, and for the purpose is much better than cast iron.

WESTERN (U.S.A.) GAS ASSOCIATION.

In last week's JOURNAL, we gave the first portion of our abstract of the "Official Report" (from the *American Gaslight Journal*) of the proceedings at the annual meeting of the above Association; and to-day we publish a further instalment.

Mr. B. E. CHOLLAR, of Topeka, Kansas, read a paper entitled "A Paradoxical Box." The ability of water to absorb ammonia from the gas, and thus become the medium of removing many times its own volume of other impurities, had been known for many years, he said, and was applied by the medium of "scrubbers" and of "washers." His paradoxical box was a washer; but was little more than a modification of Wilson's submerged plate, which was patented in 1817. A screen of fine wire cloth was supported about 3 inches from the bottom of a rectangular iron vessel; and the gas was conducted down below the screen by an iron hood. The paradoxical part of the affair was that the space below the screen was free from water when in action. The gas forced the fluid through the screen, and supported it there. When in use the apparatus was charged with water to a few inches above the level of the screen; and the gas passed steadily through the liquid in minute bubbles. The gas he manufactured contained $3\frac{1}{2}$ per cent. of sulphuretted hydrogen, and $3\frac{1}{2}$ per cent. of carbonic acid. The gas was well condensed in a spiral, consisting of about 700 feet of cast-iron pipe, before reaching the washer; and the condenser and washer together completely freed the gas from tar, and removed about 12 per cent. of the impurities.

In the discussion which followed, Mr. Forstall mentioned that he had tried a washer on this principle, and liked it so much that he intended to adopt it wherever he could. In reply to questions, Mr. Chollar said the gas should be well condensed before reaching the washer, or the screen would soon choke with tar. The box was made just as long in feet as the diameter of the connecting-pipes in inches; and he calculated to work at 1-inch pressure.

Mr. J. GIMPER read a paper describing the Claus process of purification in closed vessels as applied at Birmingham. At its close, the author exhibited a tracing of his "atomizing circulating scrubber." This consists of a large rectangular vessel divided into seven compartments, each of which is sub-divided into two parts; one being empty, and the other occupied by a set of shelves like a Coffey still. At the bottom of each empty compartment is a jet, with an arrangement for injecting water or liquor under pressure by means of compressed gas, and at the same time dividing it into fine spray or mist. The gas entering at the top flows downwards through the first empty compartment, meeting the spray of liquor; and then ascends through the shelves, passing in a zig-zag direction up to the top. It is thus deprived of the moisture taken up, and passes into the top of the second empty compartment, and so on alternately up and down to the outlet. The gas travels from left to right, and the liquid in a contrary direction. Pure water is supplied to the last compartment nearest the outlet. The overflow from this compartment passes off to a cistern, from which the supply for the next is taken; and so on up to the inlet end, where it flows off as strong liquor. A current of dry ammonia gas or strong liquor may be introduced near the inlet end if desired. Mr. Gimper also read a letter from Mr. J. R. Smedburg (written fifteen years ago), which set forth the importance of thoroughly condensing gas before scrubbing it, and of scrubbing with liquor rather than pure water; and it also pointed out the fact that an additional supply of ammonia to that furnished by the gas was required, in order to remove all the impurities by scrubbing. Sufficient ammonia must be present, in fact, to neutralize the whole of the acid impurities. He further explained that the atomizing arrangement used was invented by Mr. Chollar. This apparatus had existed—but on paper only—for fifteen years; and he contended that it was preferable to the Claus apparatus, as it did not require so much plant, and had not a set of pumps. A gas-compressing apparatus was the only mechanical part necessary.

Mr. C. M. KELLER, of Columbus, Ind., presented a communication entitled "The Cost of Electric Arc Lighting." He pointed out that the expense would vary in different localities, according to the prevailing rates for fuel and labour. The size of the plant, and especially the extent of approximation towards its maximum power, was also very important. For example a 50-light machine, when supplying only one arc light required $20\frac{1}{2}$ -horse power to work it; with 25 lights going, only $28\frac{1}{2}$ -horse power; and with 50 lights, $46\frac{1}{2}$ -horse power. The author had a 50-light Thomson-Houston and a 50-light American machine in operation; and he proceeded to give the details of the cost of running the former for the supply of 48 arc lights for twelve hours. This estimate was fairly complete, including repairs, taxes, and interest at the rate of 6 per cent. on a capital charge of £2000; and the total amounted to £2 10s. or 1s. 0½d. per lamp. The author, however, pointed out that the estimate did not include "depreciation of plant, burning of armatures, repairs on boilers, or accidents of any kind." The cost of a six-hour supply was, of course, much greater in proportion; being about £2, or 10d. per lamp. This was for street lamps burning continuously; but he also gave an estimate of the cost of working the American machine, for the supply of 48 commercial lights, turned off and on at different times, for six hours, which came to about £1 14s., or 8½d. per lamp. A fourth estimate represented the cost of working the two plants in combination, and amounted to £2 15s., or 8d. per lamp. In these experiments the consumption of coal per horse-power was 6½ lbs. of Indiana nut and slack, or 4½ lbs. of Pittsburgh lump coal. The two systems used showed no difference in respect to the lights—a current of 9·6

ampères being carried in each case; but the cost of maintenance was much cheaper in the case of the American plant. A fifteen months' trial of the Thomson-Houston method showed that the annual expense of repairs on 48 lamps and machinery was £25 or 10s. 6d. per lamp; and this did not include three lamps broken by accident, which caused an additional expense of nearly £4 10s. The repairs on the American system, as shown by one year's trial, on an average of 35 lamps, were £9 10s., or 5s. 8d. per lamp. He also proved that the American system required less power, and less attention. His charge per light, burning six hours each night, was 25s. per month.

In the course of the discussion, Mr. Dunbar said he was running an American plant at New Albany; and the consumption of fuel was 5 lbs. of coal per 2000-candle arc lamp per hour, in which time each lamp consumed $1\frac{1}{2}$ inches of carbon. His lamps would run ten hours without a change of carbon. Mr. Scofield remarked that Mr. Keller's estimate showed a large profit, as 2s. 1d. per night was a common charge for arc lights; but he had not included some items, which might alter the state of affairs. He wanted to know whether the electric light was more profitable than gas, and instanced a case where a gas company had lost more than £400 last year by electric lighting, and a local electric light company in the same town £1000 to £1200. In these cases the light was supplied rather cheaper than was done by Mr. Keller. He had not heard of any gas company failing; but several electric light companies had gone into the hands of receivers. He was therefore doubtful whether it was advisable to butt against the electric light, or to invest capital in an electric lighting plant. He was inclined to reduce the price of his gas to 6s. 3d. per 1000 cubic feet, and then let the electric light people come on, and see whether they could make a larger dividend than he could. His demand for gas had doubled since electricians appeared in his district. Mr. Ambrose said that for the last twelve months he had been keeping the books of a Coal Gas Company, and also of a Thomson-Houston Electric Light Company, being Secretary and Manager to both Companies. He was prepared to say that the Gas Company was doing the best of the two. The gas consumption had increased 20 per cent., although the electric light had done fairly well. On a capital stock of £32,000 for both companies, he could pay a dividend of more than 10 per cent. He therefore considered it was well for gas companies to take up the electric light. In another town he knew of the electric light was being worked by the gas company at a good profit. Mr. McMillan said that at Springfield an electric light company was started, and eventually bought out the gas company, though the two were actually being run as separate organizations; and he was Secretary and Manager to both. In each case the business was satisfactory. But they made the mistake of not supplying the incandescent light; and an opposition company had managed to establish themselves for this line of business. Mr. Chollar observed that one of the finest Edison plants in the western country had been put down at Topeka; and at one time he understood they had 5000 lights. Many of the customers who left him at first had returned; and his business had not suffered seriously, but was increasing rapidly. He doubted if it was much smaller than it would have been without the electric light company. Mr. Jenkins thought when it was decided to form an electric light company in Columbus, his Directors wanted to go into the business, but ultimately decided to let it alone. Since then the demand for gas had increased satisfactorily. Mr. Steinwedell said that at Quincy, Illinois, the Gas Company had bought up an electric plant of 310 lights; and he believed it was the best thing they ever did. He considered the estimates given by Mr. Keller were too low.

(To be continued.)

Register of Patents.

TREATING GAS AND OTHER AMMONIACAL LIQUORS.—Grahn, E., of Coblenz.

Germany. No. 10,684; Aug 3, 1887. [6d.]

This invention relates to the treatment of gas liquor and other ammoniacal liquors with a current of gas, in order to separate the ammonia or volatile ammonia compounds for the purpose of directly manufacturing nitrogenous manures.

In his specification (which is not illustrated) the patentee says that the methods hitherto in use for manufacturing ammonia compounds consist in separating the ammonia, which is in a free condition or in the form of volatile salts is contained in the liquors to be worked, by heating and vaporizing a part of the liquor; in then leading away the ammonia which is mixed with steam; and in condensing it thereupon by any suitable absorbents. According to his process, the ammoniacal salts are turned out by means of a current of air or gas; and the air charged with ammoniacal vapours is set free from its contents of ammonia by suitable absorbents. In passing a finely-divided current of gas through the ammonia containing liquor, the volatile ammonia compounds pass by diffusion into the gas; and a complete separation of the ammonia, without a partial vaporization of the solution, is thereby obtained. The current of air charged with ammonia or volatile ammoniacal salts is placed in contact (according to the ammonia compounds to be produced) with solid, liquid, or gaseous absorbents. By using a current of air or gas to conduct the ammonia from the liquor to be worked into the absorbent, not only the separation of the ammonia is facilitated and more completely than by the method heretofore in use of boiling, but it is also possible to avoid the stoppages produced by the condensation of the volatile ammoniacal salts and the separation of the condensing water, by which a part of the ammonia which has been distilled off is either conducted again into the distilling vessel or introduced into the absorbent. The air charged with ammoniacal vapours may thus be directly introduced into the absorbing apparatus; and, according to the absorbent used,

solid and dry ammonia compounds, or any other solutions and mixtures, may be directly obtained.

In order to explain the new method by an example, the patentee describes the process by which gas liquor is worked, according to his invention, into phosphate of ammonia or ammonia-phosphate of calcium or into artificial nitrogenous manure.

The gas liquor to be worked flows into the upper part of a vessel, constructed like an ordinary column apparatus used in the distillation of gas liquor, divided by a certain number of intermediate bottoms into several compartments, down which the liquid flows. Into the lowest compartment of the vessel, in which the liquid driven off is gathered, a finely-divided current of air is passed, more or less heated by steam—for instance, by means of a steam-jet blowing engine. The current of air, taking up the ammonia from the liquor, flows upwards through the several compartments of the column; and is thereby being continually distributed afresh into the liquor which flows down. In this way the current of air is cooled more and more, whilst losing thereby its water vapour; and it becomes enriched with ammoniacal vapours, owing to its contact with more and more concentrated solutions. The upper part of the column apparatus, into which the gas liquor flows in a continuous stream, acts therefore as a cooler and condenser, and the liquid freed from ammonia escapes continuously from the lower part of the apparatus; but, to free the ammonia which is bound to fixed salts, milk of lime is added to the solution before it flows out of the apparatus.

The intimate contact of the air and the liquor may also be effected by causing the latter to flow downward in vessels filled with coke or other material, while a current of air is blown upwards from below. The quantity of the air blown into the vessels, and the heating of the liquor, are so calculated that on one side the water flowing off is completely freed from ammonia; and on the other the escaping current of gas which is charged with ammoniacal vapours, has nearly the temperature of the entering gas liquor. In particular cases, the complete cooling of the current of gas may be effected by a special condenser.

To produce ammoniacal salts, the current of gas charged with ammoniacal vapours is placed in direct contact with the usual absorbents; and to directly produce artificial ammonia-manure, the current of gas containing ammonia is introduced into vessels similar to gas-works purifiers filled with superphosphate, double phosphate, or dissolved guano spread over hurdles. In passing through the acid absorbent spread in layers of moderate depth, the whole of the ammonia is separated from the current of gas, and a dry nitrogenous manure is directly obtained.

The advantages claimed for this method are, on the one hand, the easier and more complete separation of the ammonia from liquors, by means of a current of gas without partially distilling the liquor—that is to say, in the saving of combustibles; and on the other hand, the possibility of directly producing dry nitrogenous manures. The production of sulphate of ammonia is therefore avoided; and the sulphuric acid, which is prejudicial in artificial manure, is thereby prevented, and the ammonia directly obtained in the form of phosphate of ammonia, and in chemical mixture with the manure.

GAS MOTOR ENGINES.—Abel, C. D.; communicated from the Gas-motoren Fabrik Deutz, of Deutz, Germany. No. 11,503; Aug. 23, 1887. [8d.]

This invention relates to gas-engines in which the firing of a combustible charge takes place once in every four strokes of the piston—as in the "Otto" engine—and it has for its object "to produce a greater development of power by the formation in the cylinder of an explosive mixture rich in gas and free from products of combustion, and also to produce an increased useful effect and saving in gas consumption by the expansion of the products of combustion."

The engine is so arranged that, at the end of the expelling stroke, the portion of the gaseous products of combustion which would otherwise remain in the cylinder, are expelled more or less entirely therefrom by the introduction of atmospheric air, to which is afterwards admitted either pure combustible gas or a mixture of gas and air; the supply being cut off before the end of the suction stroke. By this means, on the following compression and working strokes, a high degree of expansion (and consequently an increased useful effect) is obtained. The front end of the engine cylinder is closed, and is provided with a suction and delivery valve, communicating with the atmosphere and with a closed reservoir; so that, at each forward stroke of the piston, a charge of air is forced thereby at a certain pressure into the reservoir. A pipe leads from this reservoir to the back end of the cylinder, where it is provided with a valve, and where it communicates with the inlet passage of the cylinder (also governed by a valve); both these valves being actuated by cams on a way-shaft, revolving at half the speed of the engine-shaft. These valves are opened when the piston arrives near the end of its expelling instroke; so that the compressed air can then pass from the reservoir into the cylinder, expelling the remaining products of combustion through the open escape-valve as the piston completes its instroke, at the end of which the air in the reservoir will have sunk to about atmospheric pressure. The escape-valve being now closed, the piston commences its suction stroke; and the valve of a gas-pipe leading into the inlet passage being more or less opened, gas (together with a greater or less proportion of air admitted by the air-reservoir valve) is drawn into the charge of air contained in the cylinder. When the piston has performed a certain part of its outstroke, the gas and air-valves are closed; so that, as the piston completes its stroke, the combustible charge in the cylinder is expanded below atmospheric pressure. Then at the commencement of the following instroke the combustible charge will first again attain atmospheric pressure, and afterwards be compressed to a greater or less degree on the completion of the stroke.

GAS-ENGINES.—Körting, E., of Hanover. No. 12,863; Sept. 22, 1887. [8d.]

These improvements consist in the means employed for operating the exhaust-valve and the igniting device, and for regulating the speed of gas-engines.

A is the frame of the engine containing the power cylinder. M is the exhaust valve, and O the igniting device; the interior construction of the latter not being shown, on account of its not forming any part of the present invention. S is the mixing-valve for gas and air, passing in

through the pipes U and T; and R, the check-valve for the gas mixture that has entered into the cylinder. On the end of the crank-shaft of the engine is keyed the spur-wheel B; and the spur-wheel C gears with it, having double the diameter of the former, and rotating on a pin fixed to the frame A. To the wheel C is secured a boss, carrying the two tappets D and E. H and F are two shafts mounted in bearings on the frame; the shaft H being passed through the shaft I, which is hollow. The shaft H is provided with the lever-arms K and G; the arm K being connected by the bar N to the stem of the exhaust-valve M, while the arm G (having a roller at its end) extends into the path of the tappet E. By means of a spring connected to the bar N, the valve M is normally kept closed, and the arm G maintained in the position in which it is acted upon by the tappet E when rotating. On the shaft I are keyed the lever-arm L, connected by the rod Q to the igniting device. P is a spring (for acting on a branch of the arm F), which keeps the arm and also the igniting device in their normal positions. For regulating the speed of the engine, the spur-wheel C has attached to it a governor, which, by acting on certain intermediate parts when the speed of the engine has become too great, causes the parts to lock the arm G upon its being pushed outward by the tappet E; the exhaust-valve being thereby maintained open, and the piston of the power cylinder prevented from drawing in new gaseous charges.

GAS-BURNERS.—Moore, D. S., of New York. No. 4245; March 20, 1888. [6d.]

This invention relates to a gas-burner which, when turned off, still admits a limited supply of gas, sufficient for a minute flame, and provided with a sliding chimney which is raised up so as to surround the small flame a short time after the main flame has been turned off.

Fig. 1 is a front view of the burner with the chimney down; and fig. 2 is a side view with the chimney up. Fig. 3 is a vertical central section of the burner proper.

The tapering plug-valve of the burner projects beyond the valve-seat at both ends, which are embraced by an oscillating frame consisting of two U-shaped pieces E having laterally projecting arms, and perforated centrally to fit upon the ends of the plug-valve. G is a pivoted link, connecting the oscillating frame to the cap, carrying the chimney H. By pulling one or other end of a chain attached to G, the chimney is raised or lowered; and at the same time the plug-valve is partially revolved. The plug D is provided with a transverse slit, connecting the inlet with the discharge-pipe, though intercepted by an axial perforation. The slit is made long and narrow at its discharge end, so as to be brought rapidly past the inlet-pipe when the plug is turned. For the auxiliary flame there is a perforation smaller than the slit in D, and connecting the axial perforation with the surface. Here the perforation joins a short groove partly encircling the plug. By means of these arrangements, enough gas can be admitted to feed the main flame; and still it can be very quickly cut off. This is necessary, because the main flame should disappear before the frame E has oscillated sufficiently far to raise the chimney up to the flame; otherwise the chimney would be injured. In order to regulate the size of the auxiliary flame there is a set screw entering the axial perforation in D, and of such a length that it may close up the perforation in it to a greater or less extent. There is also a spring between the oscillating frame and the plug, for holding the latter tightly to its seat.

GAS-BURNERS.—Williams, E. P., and Thomas, W. J., of Osnaburgh Street London. No. 5102; April 6, 1888. [6d.]

This invention relates to improvements connected with gas lighting or burning apparatus where gas is led into a closed receiver containing externally the burners—as, for example, in “sun-burners” and such like lamps. Where these are used, say the patentees, the heat generated by combustion is so intense as to carbonize the gas before it arrives at the burners; and the carbonaceous deposits formed, being of a gritty or powdery nature, are apt to choke up the burner orifices and destroy the efficiency of the lamp. Moreover, by the intense heat, the burners themselves as usually constructed are rapidly destroyed. The object of the present invention being to obviate these defects, the improvements consist, first, in applying to the closed gas receiver, means for precluding the access of deposits to the burner orifices, and, secondly, in constructing a burner for use with such apparatus, adapted to withstand the action of the heat.

Figs. 1 and 2 are sectional elevations of a “sun-burner” having external burners, though it will be understood that the means described for preventing the choking of the orifices may be applied also to certain closed lamps having internal burners.

A is a closed receiver of suitable form and material; and B are the orifices. According to the usual construction, gas is led to the receiver by a pipe P, which does not extend into the receiver, but terminates at or about its interior surface. Thus carbonaceous deposits lodged in the receiver, especially under pressure, may be easily blown into and choke the burner orifices. It is proposed therefore, to extend the pipe P for a suitable distance into the receiver; and beneath its open end is disposed a set of inclined surfaces, but preferably a truncated cone or pyramid inverted as shown at C, forming a separate chamber at the lower part of the receiver A. In some cases an additional set of inclined surfaces or part of a cone or pyramid may be used, as in fig. 2. The parts C are made of thin metal or other material adapted to withstand intense heat. At the base of the receiver is a screw plug S; so that all deposits formed are blown through the opening in the lower chamber, whence they cannot return to the burner orifices, but may be removed when required by the screw plug.

APPLICATIONS FOR LETTERS PATENT.

9480.—TOLLERTON, J., “Improvements in apparatus for the speedy application of gas to wing lights, ground rows, and to the stages of theatres and public halls generally.” June 29.

9531.—CLERK, D., “Improvements in gas-engines.” June 30.

9544.—SUGG, W. T., “Improvements in the construction of gas cooking-stoves.” June 30.

9578.—DOUGILL, J., “Improvements in gas motor engines.” July 2.

9586.—THOMAS, J., “Improvements in apparatus for carburetting gas.” July 2.

9598.—BRAITHWAITE, C. L., jun., and BRAITHWAITE, I., “Improvements in or relating to heating water by gas, and obtaining a mechanical motion on change of temperature, applicable to the regulation of gas.” July 2.

9683.—ULLRICH, J. B., “Improvements in rotary slide-valves for gas-engines.” July 3.

9696.—ATKINSON, J., “Improvements in gas-making apparatus.” July 4.

9728.—DOTY, H. H., and THE DOTY LIGHTING AND HEATING CORPORATION, LIMITED, “Improvements relating to apparatus for utilizing liquid hydrocarbons for lighting and heating.” July 4.

9749.—HAACKE, A., “Improvements in the protection of pipes or other vessels containing gases, liquids, or solids at a low temperature, and for preventing the formation of ice or the condensation of moisture on the outside of such pipes or vessels.” July 4.

HUELVA GAS COMPANY.—The annual general meeting of this Company was held in Glasgow on Friday, the 29th ult., when it was agreed to adopt the report (the principal portions of which were given in the JOURNAL last week), and to declare a dividend of 6½ per cent.

MILL LIGHTING BY ELECTRICITY.—An installation of the electric light has just been carried out in one of the mills of Messrs. Vicary, tanners, of Newton Abbot. Hitherto the gas bill for the building in which the new illuminant has been adopted has been £36 per annum. The interest on the outlay incurred, together with the cost of maintenance and renewals, will, it is said, be only £16 a year—a saving of £20 a year being thus effected. There are 82 lights in the mill, of which about 20 are of 60-candle power and the remainder 16-candle power. The dynamo is of 100-light power, and is driven by the large engine used for the machinery generally. The average requirement for the dynamo is 1-horse power for every 10 lights. There are 110 hands employed in the mill.

Correspondence.

[We are not responsible for the opinions expressed by Correspondents.]

MECHANICAL V. HAND STOKING AT THE MANCHESTER CORPORATION GAS-WORKS.

SIR,—In your issue of the 3rd inst., Mr. West questions the accuracy of my figures. Those figures do not contain, as he suggests, any outlay on retorts or retort settings. They do, however, include more men than Mr. West gives as engaged on the work; notably two sub-foremen and four men opening pipes and scouring retorts. The figures I gave, moreover, are not those of a theoretic week, but the actual cost during the nine months, with the actual amount carbonized. The nine months was the latest period of Mr. West's engagement here. The accounts were on that occasion made from June to March, instead of from June to June as previously, to bring them to correspond to the financial year of the Corporation.

Manchester, July 7, 1888.

JOHN KING, jun.,
Chairman, Rochdale Road Works of
the Manchester Gas Committee.

THE STAMP DUTIES ON TRANSFER OF STOCK IN GAS COMPANIES.—“Share Ledger” asks: “Will you confer a favour on the benighted by informing us what effect, if any, the new regulations with regard to stamp duties have on the transfer of shares or stock in gas companies? For instance, what is the present duty on a common deed of transfer on £100, or its higher or lower multiples?”

THE PHOTOMETER QUESTION AT THE GAS INSTITUTE MEETING.—We have received from Mr. W. Sugg a letter dealing with the above subject, in accordance with the intimation given by him in the JOURNAL last week; but it came to hand so late that we are reluctantly compelled to hold over this communication, as well as another which has reached us on the same matter, till our next issue.

Parliamentary Intelligence.

HOUSE OF LORDS.

MONDAY, JULY 2.

The Limsfield and Oxted Water Bill was read the third time, with the amendments, passed, and sent to the Commons.

TUESDAY, JULY 3.

The Bristol Water Bill was reported, with amendments. A petition against alterations in the Nelson Local Board Bill was presented by the Brierfield Local Board.

THURSDAY, JULY 5.

The following Bills received the Royal Assent by Commission:—Henley-on-Thames Gas Bill, Hinckley Local Board Water Bill, Newport (Mon.) Corporation Water Bill, South Lincolnshire Fen Water Bill, Stockton and Middlesbrough Corporations Water Bill, Uckfield Water Bill.

The Llanelly Local Board Bill was read a second time, and committed.

FRIDAY, JULY 6.

The opposition to the Llanelly Local Board Bill has been withdrawn.

HOUSE OF COMMONS.

MONDAY, JULY 2.

The Falkirk and District Water Bill (Lords) and the Lincoln Corporation Bill (Lords) were reported.

LONDON COAL AND WINE DUTIES CONTINUANCE BILL. On the motion of Sir R. FOWLER, the order for the second reading of this Bill was read and discharged.

STATISTICS OF METROPOLITAN WATER COMPANIES. On the motion of Mr. J. F. B. FIRTH, the following Parliamentary Papers were ordered:—

Return of the accounts of the Metropolitan Water Companies for the year ending Dec. 31, 1887 (in continuation of Parliamentary Paper No. 193 of Session (2) 1880, and Parliamentary Paper No. 129 of Session 1882); and of the area in square miles and portions thereof supplied by each Company, together with an estimate of the daily waste in gallons—waste being understood to mean that portion of the water supply which is not consumed by domestic requirements, nor trade purposes, street watering, gardens, &c., but which arises from defective mains or service pipes, inefficient plumbing, &c.

Return showing, in respect of the Metropolitan Water Companies, the maximum number of houses or other buildings supplied with water by each Company in the years 1883 and 1887 respectively, and the total amount of the rates, rentals, and any other charges received for the supply of water to houses or other buildings, excluding garden supplies, during the financial year ending in September or December (according to the date to which the annual accounts of the Company were made up), in the years 1883 and 1887 respectively; showing, in respect of each of the Metropolitan Water Companies, as regards each financial half year subsequent to September or December, 1883, according to the dates to which the accounts of the Companies were made up—(1) The total amount paid by the Company by way of dividend; (2) the rate per cent. per annum of the dividend paid; (3) the amount of share capital (within the meaning of section 39 of the Metropolitan Water Act, 1871, and including loan capital converted into share capital) paid up during the half year, in respect of capital taken up during such half year or previously by corporations or persons who, when such share capital was taken up, were shareholders of the Company; (4) whether such share capital was taken up at par, and if not, at what price per £100; (5) the amount of loan capital (within the meaning of section 39 of the Metropolitan Water Act, 1871) paid up during the half year in respect of loan capital taken up during such half year or previously by corporations or persons who, when such loan capital was taken up, were shareholders of the Company; (6) the rate per cent. per annum payable on such loan capital; (7) whether such loan capital was taken up at par, and if not, at what price per £100; (8) the amount of bonuses or other payments made to shareholders, excluding dividends, but including, in the case of the New River Company, any payments in respect of the landed estate, houses, or property of that Company not directly used for or connected with their water supply. Also, showing (a) the amount of share and loan capital respectively of each Company at the end of the financial half year next after September or December, 1883 (according to the date to which the accounts of the Company were made up); (b) the amount of such share and loan capital at the end of the last financial half year to which the accounts of the Company have been

made up and audited; and (c) the value of the share and loan capital of each Company, according to the Stock Exchange List, on or about the 31st day of December in the years 1883 and 1887 respectively (in continuation of Parliamentary Paper No. 136 of Session 1885).

THURSDAY, JULY 5.

The Lincoln Corporation Bill (Lords) was read the third time, and passed, without amendment.

Requisitions to withdraw their petitions against the Edinburgh and Leith Corporations' Gas Bill (Lords) were presented from the Edinburgh and Leith Gaslight Company and the Edinburgh Gaslight Company.

FRIDAY, JULY 6.

The Staffordshire Potteries Water Bill (Lords) was reported, with amendments.

HOUSE OF COMMONS COMMITTEE.

WEDNESDAY, JUNE 20.

(Before Mr. J. W. LOWTHER, Chairman; Mr. T. A. DICKSON, Mr. PEARCE and Mr. MAPLE.)

GAS PROVISIONAL ORDERS (No 1) BILL—THE SWANSEA GAS ORDER.
The Corporation of Swansea having raised objections to the Provisional Order applied for by the Swansea Gas Company, to enable them to raise further capital, after the Order had been approved by the Board of Trade, and submitted to Parliament for their sanction, the Confirmation Bill containing the Order was referred to a Select Committee, constituted as above, in order to allow of the opponents being heard in support of their case.

Mr. LITTLER, Q.C., and Mr. PEMBROKE STEPHENS, Q.C., appeared for the Company; Mr. BALFOUR BROWNE, Q.C., and Mr. CRIPPS for the Corporation.

Mr. LITTLER, in opening the case, said the Company was incorporated in 1830 with a capital of £6000, and with power to borrow £3000. In 1861 they were authorized to raise £100,000, of which only £6000 was treated as original capital, with a 10 per cent. dividend. As the Company had spent on works £29,000 out of revenue, further capital to the extent of £12,000 was allotted to the proprietors; the rest of the £100,000 being limited to 7½ per cent. By the Act sanctioning this, it was provided that the remaining £82,000 should be offered for sale by auction, and that the premiums should be added to the capital of the Company. They were also authorized to borrow £25,000. Since that time they had issued the whole of their capital, and had reached the limit of their borrowing powers. The premiums they obtained on their issue of capital amounted to £24,301, or close upon 25 per cent. of the entire capital of the Company. In 1885 they had exhausted their borrowing powers, and issued the whole of the remaining shares; and having since to make further extensions, they had to borrow from their bankers £6775, and had, in addition, incurred other liabilities amounting to £6446. Further they had formed a contingency fund in addition to their reserve fund; and from the year when this contingency fund began to grow to its present size, the consumers had been saved no less than £975 a year by the course the Company had taken. Exclusive of the £12,000 for the contingency fund, they owed £13,121. In consequence of the shortness of capital, they had been compelled to defer necessary extensions of works and mains. They were, therefore, obliged to apply for more money. They had originally put the amount at £75,000; but the Board of Trade, at the suggestion of the Corporation, had lowered it, without any great discussion on the part of the Company, to £50,000. This they considered would have satisfied the Corporation; but as they had thought fit to oppose the Bill now, and inasmuch as the Company would want something like from £30,000 to £35,000 in the next two years, and should certainly require the whole in the course of six or seven years, he would ask the Committee to again insert £75,000 in place of the £50,000. The Company had 65 miles of pipes, on a considerable part of which there was only a very small return. They had only 3850 consumers, and only 1140 public lamps. The entire consumption of gas in the district last year was but 191 million cubic feet; so that they only sold 2,800,000 feet on each mile of main. Swansea was extremely badly situated for making a profit, because nearly all the town was undermined, which increased the leakage, besides which there were in the borough a number of works in which gas was consumed very irregularly. Comparing Swansea with the two neighbouring towns of Cardiff and Newport, the learned Counsel said that at Cardiff in 1886 they had a sale of 402,695,000 cubic feet against the Swansea Company's 190,000,000 feet; the length of mains was only 85 miles; the number of consumers, 8841; and the quantity of gas per mile of main, 4,730,000 feet. In Newport, they had a sale of 156,674,000 cubic feet spread over 35½ miles of main; averaging about 4,400,000 cubic feet per mile. The price of gas at Cardiff was 2s. 6d., and at Newport 2s. 10d. per 1000 cubic feet. The Swansea Company's Act of 1861 fixed the maximum charge at 4s. within, and 5s. 6d. beyond the borough; the actual charges being 2s. 10d. and 4s. 4d. respectively. The present Order proposed to reduce the price to 3s. 9d. per 1000 cubic feet within, and 5s. beyond the borough. The Company were dealing very liberally with their customers. In the past year, there was a deficiency of income to the extent of 1.11d. per 1000 feet below what was necessary to pay the maximum dividend; and in the previous year there was only a surplus of 1.63d. In regard to illuminating power, though they were only bound to supply gas of 11 candles, they had been sending out gas of 14 to 14½ candles; and in order to do this, they had had to import Scotch cannel to mix with the local coal, which would only produce 9000 cubic feet per ton of 12-candle gas. He should mention that the dividends on the new capital would be 7 per cent. on what was raised on ordinary capital, and 6 per cent. on the preference capital; and if the Company borrowed, it would not be at more than 5 per cent. When before the Board of Trade, the Corporation wanted to prevent the Company spending more than £20,000 in the next two years; but the Board would have nothing to do with this, as the Company already owed £13,000. The Company also proposed before the Board to supply 14-candle gas; and with the hope of getting rid of the opposition of the Corporation, they agreed to put it at 15-candles. This, however, did not make it necessary that they should be required to supply gas of this power now; and he should prove that 14-candle gas was good enough. Supposing 14½-candle gas, they could not pay the maximum dividends; and if they had to furnish 15-candle gas, it would mean an additional cost of 3d. per 1000 cubic feet to manufacture. The learned Counsel then dealt with the petition of the Corporation, in which they said that they were advised that the share and loan capital proposed to be authorized was excessive; and they applied that the dividend on the new shares should be reduced. Why, he asked, were the Swansea Company to have less dividend than any other company in the kingdom? Seeing that the gas business was a risky one just now, and they had competition from other illuminants, he considered the dividends should be rather raised than reduced. The Corporation, in their petition, also complained of the high rate of interest proposed to be sanctioned in respect to the additional loan capital; and submitted that it should be reduced, or provision made for raising loan capital subject to auction clauses similar to those applic-

able to share capital. With the sole exception of the South Metropolitan Company, there was no gas company which was under the obligation of issuing loan capital by auction; and he ventured to say that it was a useless and absurd obligation. The petitioners also complained "of the high maximum price proposed to be authorized;" and they said they were advised that "the price could be greatly reduced without prejudice to the maximum dividends, if the undertaking were more economically managed." He (Mr. Littler) was more surprised at this than he could tell, because some years ago the Corporation approached the Company with a view to purchasing the works. The Company did not desire to sell, though at that time they were certainly more disposed to do so than now. They, however, allowed Mr. G. Livesey to inspect the works on behalf of the Corporation. [The learned Counsel here read a long extract from Mr. Livesey's report, in which he stated that the concern seemed to be so well conducted that he would only say possibly some economies might be effected in the management; and further on he said: "I have made a thorough examination of the works, and must say it is very unusual to find an old-established gas-works in such substantial and excellent order."] This report was dated Aug. 26, 1885. In the face of this report, he considered it was perfectly monstrous on the part of the Corporation to put the Company to the expense of appearing there to negative such an allegation. The Corporation also submitted that the Company should adopt the sliding scale, and that a reasonable standard price (not exceeding the price now charged) should be inserted in the Order. First of all, there never was an Order which put the standard price at the figure now charged by the Company; and, secondly, there never was an Order or a Bill in which the sliding scale was imposed upon a company who did not desire to have it. The present price was notoriously not one by which the Company could earn their dividend; and the standard would have to be something between the existing price and the maximum, because they had to allow for contingencies and risks. It seemed to him that the sliding scale tempted people to false economy. What they proposed, he believed would be better both for the consumers and the Company; and he hoped Parliament would not compel them to adopt, for the first time in the case of a gas company, that which they believed would be worse for the particular Company concerned and the public. Further on in their petition, the Corporation desired that provision should be made to enable them to purchase the gas undertaking on fair terms, and that proper clauses should be inserted in the "Bill or Order" to enable them to effect such purchase. He supposed that the Corporation were ignorant of the fact that no provisions as to purchase were ever inserted in any Order, and they also ought to have remembered that no provisions for compulsory purchase had ever been inserted in a Gas Bill, and there was hardly an instance of compulsory purchase of a water company. In conclusion, he should mention that on the 16th of April, this year, the Town Clerk wrote to the Company saying that the Committee of the Town Council were willing to withdraw all further objection to the Order provided that the illuminating power of the gas was fixed at 16 candles, the maximum price within the borough put at 3s. 6d., and provision made for an additional testing-place other than at the Company's works. Although there were then only three things they thought fit to bring forward, they were now making all the allegations to which he had alluded. He would ask the Committee to disregard these allegations, to give the Company a reasonable amount of capital; and not compel them to put the illuminating power above what it was now. They did not say there had been any complaints as to illuminating power; and he questioned whether they could get a consumer to say that there was any complaint.

Mr. F. J. C. Scott, examined by Mr. PEMBROKE STEPHENS, said he had been Vice-Chairman of the Company for twelve years. Having given evidence as to the capital powers of the Company (which were given in detail by the learned Counsel in his opening statement), he stated that, but for the existence of the contingency fund, the Company would not have been able to carry on so long as they had done; and it was therefore absolutely necessary for them to come to Parliament for additional capital. In their dealings with the district the Company not only fulfilled all the obligations put upon them by Parliament, but had supplied gas of a quality considerably in excess of what they were required to give, and had charged prices much below those to which they were entitled. They had now, in fact, reached a point at which they did not earn their statutory dividend; and it was impossible for them to go lower.

Cross-examined: He did not think it would be better for the consumers to have 16-candle gas, because they would have to pay more for it. The insertion of 3s. 6d. as the maximum price in the borough might lead the Company into bankruptcy in the event of a war or anything else sending up the price of coal, more especially looking to the addition they had now to make to the illuminating power of their gas. In regard to the sliding scale, he differed from Mr. Livesey in the opinion that it ensured the practice of enterprise and economy. As to raising borrowed money by auction, he thought this would be detrimental to the Company, because the premium would not be sufficient to pay the extra interest—that was to say, if £100 fetched £120, this might not be sufficient in calculating to pay the money borrowed at 3½ per cent.

Mr. Thornton Andrews, M. Inst. C.E., said he had occupied the position of Secretary and Engineer of the Company for 32 years. When he was appointed, the works were not in a satisfactory state; and the supply of gas was insufficient for the demands of the consumers. In consequence they had to make very considerable extensions. In the 31 years from 1830 to 1861, a sum of £29,000 was expended out of profits. The shareholders during this time had not received their full statutory dividends; the average dividends amounting to only £4 11s. 4d. per annum.

The CHAIRMAN here intimated that the Committee had come to the conclusion that practically the whole question at issue between the parties resolved itself in four points—viz., the amount of capital, the maximum price to be charged, the illuminating power, and the provision of an additional testing-place. It would be convenient if the attention of the Committee were directed to these points only.

Mr. BALFOUR BROWNE said there was also the question as to whether the money borrowed should be raised in the ordinary way, or under the auction clauses; and he was going to ask that the sliding scale should be imposed on the Company, under which there would be an initial, but not a maximum price.

The Committee having consulted, The CHAIRMAN said that, of course, they could not exclude anything Mr. Balfour Browne had to say as to the auction clauses; but at the same time they did not attach any very great weight to the learned Counsel's views on these clauses as applied to borrowing powers. As to the question of the maximum price, the Committee thought they should elect to fight the Order either upon that or upon the sliding scale.

Mr. BALFOUR BROWNE replied that he should, of course, at once elect to fight on the principle of the sliding scale; but if the Committee should be against him on this, surely they would hear his evidence that the maximum price proposed was too high.

The CHAIRMAN assented.

Examination resumed: There were general conditions which made it difficult for Swansea to have a high illuminating power. First, the local

coal yielded gas of poor illuminating power—12½ candles was the average; and they had to supplement this coal by Scotch cannel. The higher they put up the illuminating power, the more of this foreign element they had to import. Any increase of the standard of 14 candles would require an addition to the initial price. If they used 10, 15, or 20 per cent. of cannel, according to the quality of gas required, they would either make the coke from the local coal useless, or would have to destroy the cannel coke manufactured. Therefore they must ascertain the loss of coke in estimating the increased price or value of a standard candle. The Swansea district was not residential, but consisted mostly of the labouring and manufacturing class, which made a high quality gas unsuitable. In the large works, the men burnt the gas out of open stand-pipes, cocks, or large taps; and therefore gas of more than 14-candle power would not only be wasteful, but a nuisance. The consumption from 25 of the works and the public lights was one-third of that consumed by private persons. With respect to the testing of the gas, it was examined daily by the Company; and an officer was appointed by the Corporation to look after their interests. The Company had not had any formal complaint from the Corporation that the gas was not of the required quality. The total share capital of the Company in 1861 was £21,300; in 1871, £67,750; in 1881, £115,360; and in 1885, £125,000. The make of gas for 1861 was 41 million cubic feet; for 1871, 94 millions; for 1881, 171 millions; for 1885, 210 millions. In 1861, the price of gas was: In the borough, 4s.; outside, 5s.; to the Urban Sanitary Authority, 3s. 10d. In 1871, it was 3s. 6d., 5s., and 3s. 3d. respectively. In 1881, it was 3s. 3d. in the borough; and 2s. 9d. to the Sanitary Authority. In 1885, 2s. 10d. to the private consumer; 3s. 4d. to Sketty; 4s. 6d. at the Mumbles; and 2s. 6d. to the Urban Sanitary Authority. While the make of gas had augmented five times, the rental had only increased from £6689 to £28,231. The increase of consumption had been 22·8 per cent. in the last seven years; and the increase of rental 11·3 per cent. This was owing to the reduction in price. If they had kept up the price they were charging in 1881 to the present time, they would have been earning £3979 more than they were doing; and this had gone to benefit the consumer. The Order prescribed a 15-candle gas, which meant 15 candles actual. He estimated the cost for every additional candle at 2½d. per 1000 cubic feet, including the loss of coke due to the use of extra cannel. They would now have to face further expenditure, and should require to erect the twelve benches, each setting containing seven through retorts—being equal to 168 mouthpieces. They required a new coal-store, an extension of the retort-houses, new washers, and would also have to lay down additional mains. They proposed erecting sulphate of ammonia apparatus; and would want some new services, consumers' meters, and gas-stoves. The total cost of all these things he estimated at £24,620. Then they wanted some working capital; and for this he had put down £5900. The liabilities over on June 30 last year—£7759—made the total amount £37,372. This would only leave a margin of £13,000 from the £50,000. Taking the actual increase during the last five years, the £50,000 plus the £12,400 borrowing powers, would only last between seven and eight years. But if they obtained the limit that was usual, of ten or twelve years, then they would require £75,000, and £18,750 borrowing powers. As to the sliding scale, he did not think it would be suitable to the circumstances of the Company. He did not think it reasonable that they should at one and the same time be asked to supply a higher quality gas and have the price cut down. In regard to the public lighting, after setting a three years' contract with the Corporation, complaints were made of the lateness of the hour at which the lamps were lighted, and the Company consented to light them an hour earlier for three months in the year; so that they were absolutely lighting the lamps for 91 hours over time.

Cross-examined: Witness was aware that 16 candles was the illuminating power of the gas in Cardiff, and the maximum price authorized was 3s. 6d. per 1000 cubic feet. Supposing the Committee desired that the standard should be 16 candles, they would have to make it higher than that, and would require to use 20 per cent. of cannel. If they supplied gas of this quality, the consumers' burners would have to be altered. They used with the Welsh coal 6·30 per cent. of cannel. The average make had of late years been 9360 cubic feet per ton. Of the one-third consumption which he attributed to "26 works and public lamps," they received from the former £5112, and £3742 for the street lamps. Of course, the public lights were supplied at a lower price. He admitted that they had had complaints from consumers; but in some cases the fittings were in a wretched state. In the two half years in 1887, they could not pay the dividends. Asked whether they had any arrears of dividends, he said they had all been paid up. The Company had made up a contingency fund of £13,900 out of surplus profits, and had expended it on works. The gas consumers had not lost this amount; they had gained by what it had produced. The reserve fund was different from the contingency fund. It was invested in Consols, and was intended to meet any deficiency in dividends. He agreed that they ought not to have reduced the price 2d. per 1000 cubic feet in October, 1886, by which proceeding they were out of pocket to the extent of £1600. He did not think that 33 per cent. of margin in manufacturing power was unusual. The 168 mouthpieces he had alluded to, would enable them to produce 1,250,000 cubic feet of gas. The 907,000 cubic feet given by Mr. Livesey in his report, as being the largest daily make, referred to three years ago. The make had increased since then. Up to the present they had not had washers; but he thought they ought to have them. The new mains were necessary to supply the new works, additional public lamps, &c. The sulphate plant had become worn out; being an old apparatus put up in 1878. Witness was about to be cross-examined on the question of the sliding scale when

The CHAIRMAN said that the opinion of the Committee was decidedly against Mr. Balfour Browne; and they considered it would be an undesirable thing to force on the Company.

THURSDAY, JUNE 21.

Mr. Thornton Andrews, re-examined, said that the maximum prices of 3s. 9d. and 5s. per 1000 cubic feet were fixed in order to meet such contingencies as a rise in the prices of coal, labour, and materials. The Company did not expect to have to pass through a worse crisis than that of 1873, when coal was at 23s. a ton. At that time they were able to sell gas at 3s. 9d. and 4s. A reduction to 2s. 10d. was brought about by the action of the Corporation and a few consumers, who thought that 3s. was too high.

Mr. BALFOUR BROWNE: In 1885, when the price of gas was 3s., the actual revenue amounted to £27,147; in 1887, with the price at 2s. 10d., the income amounted to £38,331. Therefore, with the reduced price you had £1000 extra money.

Witness: With an increased consumption.

Mr. PEMBROKE STEPHENS: An increased make, of course, means increased expense.

Mr. BALFOUR BROWNE: It shows that the increased consumption enabled you to overcome your total loss, and get £1000 besides.

By Mr. DICKSON: They had now 2000 tons of breeze produced from coal lying upon the works; their coke had been as low as 5s. per ton; and

this he attributed to the poverty of the coal, and the necessary employment of cannel.

Mr. Alfred Lass, F.C.A., gave a statement of the Company's capital and premiums received. As to expenditure, up to December, 31, 1887, after writing off £12,957 17s. 5d.—the amount taken from the contingent fund—the capital expended was exactly the amount of the share, loan, and premium capital £149,801 3s. During the last five years the increase in gas sold had been at the rate of 4·89 per cent. compound. The reserve fund became full in 1885. As to the contingent fund, if fresh capital had been called up, instead of using the £13,000 from this fund, interest would have had to be paid, which would have come out of the consumers' pockets. Assuming this £13,000 had been sold by auction, they might perhaps have reduced it to something like a 5 per cent. investment. Taking the capital at 7½ per cent., this would have sold by auction at about 30 per cent. premium; and they would have had an additional burden of £647 thrown upon the concern in the shape of dividend. They had had the maximum dividends for many years; but the dividends had been paid free of income-tax. The cost of making gas was 27·5d. per 1000 cubic feet; and they had realized by the sale of gas 35·43d.—leaving a profit of 7·92d. The dividend and interest amounted to 11·19d.; and this showed a deficiency on the sale of gas alone of 3·27d. This was reduced by the meter-rental, a small profit on fittings, and the interest on investments, by 2·16d.; so that the net deficiency for the year ending Dec. 31, 1887, amounted to 1·11d. The unaccounted-for gas was 5·68 per cent. The amount of 10 per cent. capital at Swansea was unusually small—£6000 out of £100,000. The interest-bearing capital was only £510s. 8d. per ton of coal carbonized. He thought that the Company ought to be allowed a reasonable maximum price.

Cross-examined: The deficiency of 1·11d. he had mentioned amounted to £884 11s. 9d. He admitted that the Directors' fees were increased during the years 1885-7 by £200; that there were law expenses in 1887 amounting to £495; and that the Company paid the income-tax of £279 for the year 1887. These items amounted to £974. Of course, they could have met the total dividend if these expenses had not been incurred. Coal cost in the year ending June 30, 1885, £12,439; ending June 30, 1886, £12,708; and ending June 30, 1887, £12,028, which showed that they paid less for the last year than the first-named under this head. The wages in 1885 were £4115; and in 1887, £4121.

Mr. R. P. Spice, C.E., said he thought that Mr. Andrews put the whole matter very fairly as to the extensions required at the works. In his judgment the £50,000, would not last so long as seven years. He considered the standard of illuminating power ought not to be above the ordinary one of 14 candles; and as to the price, he thought the Company had made a mistake in reducing it to 2s. 10d.

Cross-examined: The witness thought the consumers would prefer a 14 or 15 candle gas to anything higher, if the price had to be raised.

Mr. G. W. Stevenson, C.E., was also of opinion that the illuminating power and the price must go together; there must be an increase of price, because there would be an increase of cost. In regard to capital, he agreed with the evidence already given; and also as to the expenditure which would have to be incurred during the next two years. The interest of the Company was to spend as little capital as possible.

Cross-examined: He did not think the purchasers of the gas were the people to be consulted as to the illuminating power, as they did not know what was good for themselves in this respect.

This concluded the case for the promoters.

Mr. BALFOUR BROWNE said he did not think it would be necessary for him to call any evidence. As to the question of illuminating power, when the Company were before the Board of Trade they were willing to accept a higher standard than now; and this because the Corporation dared to oppose the Order. He thought he had shown that they were anxious to have an illuminating power of 15 candles. The learned Counsel next dealt with the question of capital; criticizing in detail the various requirements, as given by Mr. Andrews. He remarked that, according to Mr. Livesey's report, they had but three years ago a reserve power of 33 per cent. in the works; and he contended that only 8 per cent. of this was now exhausted. As to the contingent fund, the Company had actually been transgressing the law; for this fund had been taken out of the consumers' pockets. As to the income-tax—though it was a small matter comparatively—it should have been applied to a reduction of price. He contended that it had been improperly taken from the consumers to save income-tax to the shareholders. As to the maximum price, the learned Counsel maintained that it could not, allowing an ample margin, come to more than 3s. 4d. As to the testing place, if the testing was to be effective, it could not be done at the works.

The room was then cleared. On the parties being called in,

The CHAIRMAN said the Committee had decided to retain the amount of ordinary shares or stock at £50,000, not £75,000; the borrowing power to be £12,500. With regard to the quality of the gas, they had decided to confirm the Order of the Board of Trade, and retain the power at 15 candles. As to the price, they would vary the Order by reducing it from 3s. 9d. to 3s. 6d. Then, in regard to testing, the Committee wished a clause to be brought up in accordance with the clause in the Model Gas Bill providing for testing the pressure. They did not vary the Order in respect to the place of testing.

The clauses and preamble were then read and agreed to, with the amendments; and the Chairman was directed to report the Bill, as amended, to the House.

THE ROCHDALE CORPORATION GAS UNDERTAKING AND THE RELIEF OF THE RATES.—A Rochdale newspaper remarks that the annual statistical table of the Rochdale Gas-Works which has lately been issued gives a better view of the operations of the department than the usual accounts, and some interesting comparisons with the work of previous years. The actual quantity of gas sold last year was 267 million cubic feet, as against 264 millions in the previous year, and 252 millions in the twelve months preceding. The quantity registered at the works as being made was 331 millions last year, compared with 316 millions the year before. It is one unsatisfactory feature in last year's proceedings that the loss by leakage was so great; amounting to no less than 13·41 per cent., as compared with 10·54 per cent. in the preceding year. It is worthy of note that since 1885 it has not been found necessary to use a single ton of cannel. The writer proceeds: "The advocates of a reduction in the price will be confirmed in their opinion by the figures, which show that the net cost of gas per 1000 cubic feet, reckoned on the quantity sold, and including payments to the sinking and reserve funds, has only been 1s. 10½d., while the cost reckoned on the quantity made, and excluding payment to the two funds mentioned, has only been 1s. 6½. This being the case, one would have thought a reduction to somewhat less than 3s. might very well have been made in the selling price, and would have been good policy, seeing how fractional has been the increase in the consumption during the year. The interesting fact is stated that since the works came into the hands of the Corporation the Committee have paid over to the finances of the town, out of their profits, the vast sum of £215,865; being more than the whole amount spent on the works."

Legal Intelligence.

HIGH COURT OF JUSTICE.—CHANCERY DIVISION.

SATURDAY, JULY 7.
(Before Justice North.)

WASTE WATER-METER COMPANY, LIMITED, v. UNIVERSAL WATER-METER COMPANY, LIMITED.

This was an action for an injunction to restrain the defendants from infringing the plaintiffs' patent; the usual issues being raised by the defendants as to validity, &c. The defendants having now submitted, the matter came before the Court as a "short cause;" the terms of the order being agreed upon. An order was taken for an injunction, restraining infringement, and the delivery up of the infringing machines, and circulars, &c.

Mr. CHADWYCK HEALEY appeared for the plaintiffs.
His LORDSHIP made an order in the terms arranged.

HIGH COURT OF JUSTICE.—QUEEN'S BENCH DIVISION.

TUESDAY, JUNE 26.

(Before Justices WILLS and GRANTHAM.)

WRIGHT v. SOUTH METROPOLITAN GAS COMPANY.

A QUESTION UNDER THE EMPLOYERS' LIABILITY ACT.

This was an appeal from the decision of the Southwark County Court in an action brought by the plaintiff, a workman in the employ of the defendant Company, for compensation for injuries alleged to have been caused by their negligence. The amount claimed was £210; and the jury awarded him £200.

Mr. ADDISON, Q.C., M.P., in support of the appeal, argued that there was no evidence to go to the jury as to the alleged defective condition of the defendants' plant, or of negligence on the part of their servants. The plaintiff's injuries were caused by the falling upon him of one of the retort-lids, the fixing of which he contended was defective, owing to the negligence of the men employed at the retorts. This, the learned Counsel argued, was not made out by the evidence; and therefore he claimed that he was entitled to judgment.

Mr. MOYSES addressed their Lordships in support of the verdict; but had not finished his remarks when he received an intimation that he had said sufficient.

Justice WILLS, in giving judgment, said the case was eminently one for the decision of the jury. It seemed to him that there was abundant testimony of the existence of a defect; and it would require a very long argument and a great deal of evidence to convince him that it was not perfectly easy to devise some mechanical means which would not expose those who were employed about the Company's works to the danger caused by such defects. Therefore the application would be dismissed with costs.

Justice GRANTHAM concurred.

The appeal was accordingly dismissed.

CENTRAL CRIMINAL COURT.—FRIDAY, JULY 6.

(Before Mr. Justice Hawkins.)

THE SALFORD SCANDAL.—SENTENCE ON MR. SAMUEL HUNTER.

To-day, *Samuel Hunter*, formerly Gas Engineer of the Salford Corporation, who pleaded guilty at the March Sessions of the Court to obtaining property by false pretences, to uttering (at Common Law) a forged document, and to perjury, was brought up for sentence. The circumstances under which the prisoner stood at the bar are in the recollection of our readers; and the particulars of the indictments to which he pleaded guilty, appeared, with a full report of the proceedings at that stage, in the JOURNAL for March 27 last (p. 564).

Sir CHARLES RUSSELL, Q.C., M.P., Mr. POLAND, Mr. M'KEAND, and Mr. RICHARDS appeared on behalf of the Salford Corporation; Sir HENRY JAMES, Q.C., M.P., and Mr. FORREST FULTON, M.P., for the prisoner; and Mr. J. W. M'CARTHY for parties interested.

Justice HAWKINS, immediately on taking his seat on the Bench, said the first thing he desired to do was to hand to the Counsel in the case, if they desired to see it, a packet, without any note, but enclosed in an envelope stamped "Town Clerk of Salford." He had opened it, thinking it might be of some importance, as it looked like an important matter; but he found it contained a large sheet of paper with, more or less, cuttings from newspapers. He had not taken the smallest further notice of it; nor had he read them. It was a wrong thing to communicate to a Judge in this way; and he had not therefore even read one part of it. He could not have much doubt where it came from.

Sir C. RUSSELL, on the packet being handed to him, said that, on looking at it, one could see at once that it could not, in the slightest degree, be traced to any such unworthy or improper objects as his Lordship suggested.

Justice HAWKINS said he only wanted to know why anyone should trouble him to read it.

Sir C. RUSSELL said he had suggested to him that, on some application being made to his Lordship as to naming a day for passing sentence, it was mentioned, by the gentleman who had waited upon his Lordship from the solicitor in London, that comments had been made as to delay in passing sentence.

Justice HAWKINS said he knew nothing of such comments, and should not heed them. For the convenience of Counsel on both sides he had mentioned the matter; but whether the object in sending the packet was to influence him one way or the other or not, it was a stupid thing for anyone, knowing that a man was under conviction and awaiting sentence, to communicate with the Judge, except in open Court.

Sir C. RUSSELL said he had very little to trouble his Lordship with, but merely to remind him what the facts of the case were. The prisoner held the position of Gas Engineer of the Salford Corporation, and had been in their service from the year 1875, receiving a salary of £700 a year, with a sum of £100 for cab hire, and certain other small allowances. He was charged by Mr. Ellis Lever with having, in the discharge of his duties as Gas Engineer, improperly received certain moneys of persons who had contracts with the Corporation. The prisoner prosecuted Mr. Ellis Lever nominally for libel; and the case was tried before Mr. Justice A. L. Smith at Manchester, when the prisoner was under examination, having been previously examined at the Police Court. In the result the jury acquitted Mr. Ellis Lever. The indictment against the prisoner charged him with having committed perjury before the Justices; and to this he had pleaded guilty. It also charged him with having committed perjury in his evidence before Mr. Justice A. L. Smith. To this he also pleaded guilty. As regards the perjury, it was in both cases in furtherance of a criminal prosecution by which he had sought to fix the guilt of libel upon Mr. Ellis Lever. In a second indictment the prisoner had also pleaded guilty to receiving certain moneys by false pretences; and to a third he had pleaded guilty—admitting forgery at Common Law, such forgery being the putting forward, to the firm of Messrs. Pope and Pearson, Limited, a letter purporting to come from, and to be signed by the Chairman of the Salford Corporation Gas Committee, containing

the statement that he (Hunter) had the authority of the Salford Corporation to receive certain moneys by way of commission. The prisoner was also indicted under the statute in relation to the ordinary forgery; but, in the opinion of his learned friends who were with him—an opinion in which his Lordship had been good enough to express his concurrence—they did not think the forged authority was such an authority for the payment of money as to bring it within the statutory provisions of the criminal law. Accordingly, they did not offer any evidence on this matter; and with reference to it the prisoner had not pleaded guilty. These were all the facts of the case, so far as he had any right to go into them at that moment. In short, the prisoner had pleaded guilty to perjury before the Justices and also before Mr. Justice A. L. Smith, and to the indictments for obtaining money by false pretences and for forgery at Common Law. When the matter was previously before the Court, Sir Henry James (who appeared with Mr. Fulton for the prisoner) made an application to his Lordship to postpone sentence in order that the prisoner might pay back the commissions he had received, and that the Chancery action which was then pending might be forwarded.

Justice HAWKINS remarked that he understood it was rather a suggestion which was acquiesced in.

Sir C. RUSSELL said he certainly did not oppose it. He would content himself with suggesting (unless his learned friend Sir Henry James obliged him to say more) that in the Chancery proceedings nothing had been done beyond this: The suit was still going on; some accounts had been delivered as particulars in the action; and, so far as they could judge, it had to proceed in its regular course.

Sir H. JAMES asked permission to say a few words which he hoped would result in mitigation of the punishment which had to be passed upon the prisoner. He had no particular criticism to offer upon what Sir Charles Russell had said; but perhaps his learned friend would not object to his referring to the matter of the money restitution, as he wished to avoid the idea that the prisoner had fallen away from the undertaking he had given on the previous occasion when he was before the Court. He (Sir H. James) suggested that the money sought to be recovered by the Chancery suit ought to be paid; and that the best course to take would be as the proceedings in Chancery would, as usual, be of a somewhat lengthy character, that there should be some arbitrator appointed to determine the amount due. With this view, a letter was written on the 12th of April, dealing with the suggested appointment of an arbitrator; this having specially met with his Lordship's acquiescence. The offer had, however, been declined. He was quite sure that those who had declined it did so from a sense of right. However, this was the result. The Chancery suit had not been concluded, but no delay had taken place in consequence of any act of the prisoner. He (Sir H. James) was sorry the amount had not been ascertained; but he did not wish to say more than that no act of the prisoner had prevented it. He had now only to deal with one or two facts connected with the matter in excuse of the prisoner's conduct. His learned friend Sir Charles Russell had stated that no evidence had been offered on the indictment to which the prisoner had not pleaded guilty. The fact was the prisoner did receive commissions when acting as a servant of the Salford Corporation, and when representing the interest of the ratepayers, for he was their Manager. The prisoner had been for 25 years engaged in similar pursuits. He had managed gas companies; and he (Sir H. James) believed he had the acquiescence of every one when he stated that, with the exception of what had occurred at Salford, the prisoner's character was without attack and without taint. He would add that they might take it that, as far as the interest of the Salford Corporation was concerned, except in this one particular, the prisoner had served them faithfully; that the gas-works had, under his management, become prosperous, and a benefit to the ratepayers; and that, apart from these transactions, the prisoner's conduct had been all that could be desired. Of course, this was a very grave matter. The commissions had been received, and the prisoner had received them. In doing so, he had acted very improperly; and when the charge was made, the prisoner no doubt showed great want of moral courage (perhaps his Lordship would think it was worse than that) in endeavouring to defend his position. Under these circumstances, the prisoner had pleaded guilty to some of the charges made against him. He (the learned Counsel) would add—although he did not know whether or not it would affect his Lordship's sentence—that, of course, Mr. Hunter's ruin was complete. He had lost his position; he would be removed from the roll of Justices of the Peace; his home had been broken up; and for the future his life was brought to a close, so far as regarded his ever occupying again any honourable position. He would also mention the extreme gravity of the prisoner's position now with regard to his health, and the very serious effect which a lengthened punishment would have upon him. He had been in custody since the 3rd of February last, and his property had been subject to great depreciation. His home being broken up, of course his family and others had suffered as well as himself. These were all matters which he (Sir H. James) ought to mention, and which he hoped would be taken into consideration by his Lordship.

Sir C. RUSSELL stated that, so far as the Corporation were concerned, there was no desire to mix up the question of the prisoner's punishment with the question of money at all; and in regard to the provision for arbitration, he would point out that, of course, the prisoner was the person who best knew what amount he had received. He had had an opportunity of paying the money in the Chancery matter; but he had not done so. The amount proved was £1215 in one isolated transaction.

Sir H. JAMES said that with regard to there being any suggestion that the prisoner had declined to pay money, he would read a passage from a letter of the 12th of April from Messrs. Bowden and Walker to Mr. Graves (the Town Clerk of Salford): "We trust that the suggestion we have thus made will be accepted; but if the Corporation should decline to accept it, we feel that we ought to bear in mind the views that appear to have been in Mr. Justice Hawkins's mind, and therefore we shall be willing to agree to the nomination of an arbitrator who shall proceed at once to ascertain the exact amount received from the commissions, or to consider favourably any other course you may suggest to bring the litigation in Chancery to a speedy conclusion." He would now ask permission to call evidence with regard to the prisoner's health, and to his general character.

Dr. Raitt was then called, and, in answer to Sir H. JAMES, stated that he was a medical man practising in Manchester, and that the prisoner had consulted him on several occasions. He first saw him about two years ago, and had attended him up to the beginning of last year. He had visited him since he had been in custody, but not professionally. He was suffering from the complete destruction, from inflammation, of the left kidney, the result of calculi, or calculus, or stone in the kidney. It would never do for the prisoner to put off the warm clothing which the witness had advised him to put on. Prisoner had had, to witness's knowledge, considerable shivering attacks. Long imprisonment would tend to bring on these attacks, and would ultimately destroy him. He had, in fact, now only one kidney.

Mr. J. Makinson, Justice of the Peace for and also ex-Mayor of the Borough of Salford, and Vice-Chairman of the Gas Committee, also

deposed to having remembered when Mr. Hunter came to Salford in 1875, as the Manager for the Gas Committee. For anything he knew to the contrary, he always considered him to be a man of good character; and he believed he always served the Corporation faithfully, and the gas-works under his management had become very prosperous.

Mr. Jenkins, also an Alderman of Salford, a Justice of the Peace, and a member of the Gas Committee of the Corporation, concurred with Mr. Makinson in what he had stated with regard to the prisoner, and said the character that the prisoner had borne, apart from the transactions now before the Court, had been good, so far as he knew.

Sir C. RUSSELL said he only desired that the facts should be ascertained and put before his Lordship's mind; and he would merely remark that the prison doctor was present if his Lordship thought it desirable to hear his views upon the prisoner's health.

Justice HAWKINS then proceeded to pass sentence on the prisoner. He said: Samuel Hunter, it is a very painful thing to me to have to pass sentence upon a man whom I have no reason to doubt had, up to the period when these transactions commenced, borne a good character for honesty and integrity; and I have no reason to doubt that in all other respects than that upon which you have been found guilty, upon your own confession, you have done all in your power to advance the interests of the gas undertaking whose Manager you were. But, unhappily, somewhere about ten years ago, being a Gas Engineer, and in a position to exercise considerable influence over the contracts which the Corporation of Salford might be disposed to make, or which they were invited to make with colliery owners, you did that which every man must know to be a crime against his employer; that is to say, you entered into negotiations with colliery companies and with Messrs. Pope and Pearson, Limited, to receive from them commissions of not less than 10d. per ton upon all coals which they supplied upon contracts to the Salford Corporation—these contracts amounting altogether to 29,000 tons. It is true that the contracts extended over three years; and from time to time you received cheques for amounts of commission without saying a word to your employers, and without bringing the fact directly to the notice of Messrs. Pope and Pearson. The former Manager of the colliery company (I am not prepared to mention his name, because I know not how far he was acquainted with this matter) died, and a new Manager was appointed in his place. Towards the close of 1879 and the beginning of 1880, it is quite certain that the bargains you had made had come to the knowledge and were communicated to Mr. Pope, who, although he was only a member of a limited company, nevertheless took an active interest in the colliery affairs. He was immediately struck with (to use, I think, his own expression) the wickedness of the bargain which had been made and entered into with you; and there can be no doubt that it was a very dishonest bargain, because if a person who is employed to buy from those who are to serve his employers insists upon having a commission upon the goods supplied, it makes it absolutely certain that those who have to supply the goods sell them at a dearer rate than they would do if no commissions were paid. In truth, it is depriving those who buy of the amount of commission which is paid to their servant. I take this to be in itself a very dishonest course of dealing; and I am perfectly satisfied that you must have known, at the time you were receiving the various cheques that were paid to you, that it was so. But immediately before the last contract was completed, and before you received the last two cheques due to you for commission, it came under the notice of Mr. Pope. He called the attention of those who had the management of the colliery company to the fact; and the company passed a resolution that no further cheques for commission should be paid to you unless with the sanction of the Salford Gas Committee. This was the substance of the resolution that was passed. You were informed of this resolution, and were told that you would have no more cheques paid to you until that sanction was obtained. It was thought you would get it; and a form of letter was proposed, and ultimately you sent back a letter purporting to be signed by Mr. W. Sharp, the Chairman of the Gas Committee of the Salford Corporation, intimating that there was no objection to the bargain which had been made for your receipt of the commission, and stating that no objection would be interposed to your receiving what might become payable to you under that corrupt bargain. The letter which you so produced had this effect. It was accepted as a genuine letter; and, upon the strength of its being genuine, two different cheques were paid to you, amounting altogether to very nearly £500. That letter was a forgery—you forged the name of Mr. Sharp to it; or, if you did not write the name yourself, you uttered it, perfectly well knowing that it was forged, and therefore you were guilty upon the two indictments to which you have pleaded guilty. You were guilty of having forged an instrument, not so as to make you liable to the penalties which are the consequences of a felony, because a legal technical objection prevented that; but you were guilty of what is known as a forgery at Common Law, which would have subjected you to a long term of imprisonment. By means of this forgery—that document, being believed to be genuine by those who had it handed to them—you obtained these two sums, amounting, as I have already said, to nearly £500, by false pretences. These, stated shortly, are the matters with which you are charged, which appear on the depositions, and to which you have pleaded guilty so far as regards the indictments charging you with forgery and with obtaining money under false pretences. If the matter had stopped there, your offence would have been a very grave one, and you would have been liable to very severe penalties; for you had obtained cheques or valuable securities for money by false pretences, which is an offence which the Legislature has left in the discretion of the judge to punish with penal servitude. For your Common Law forgery you could not have been sentenced to penal servitude, but you might, as I have already told you, have been sent to prison for a very long term. But the matter does not rest there. Things went on until the end of the year 1886 or the beginning of 1887, when some inquiry was made in reference to the dishonest transactions to which I have referred; and a Mr. Ellis Lever was active in making charges against you. And it is clear from what has transpired, and from what has been set forth upon the depositions, that he published of you that which you alleged to be libellous; that is to say, he imputed dishonest conduct to you in having surreptitiously and fraudulently obtained this commission of 10d. per ton upon the goods which had been supplied to your employers. He avowed that this was so. You declared it to be false; and you took the proceedings which led to the commission of the perjury for which you are indicted, and to which you have also pleaded guilty. You caused a summons to be issued against him for having published respecting you an infamous libel which was untrue, and you summoned him before the Magistrates; and both before the Magistrates and before the Judge who tried the matter, you committed that perjury which is now alleged against you. On the trial of the indictment, a plea was put upon the record justifying the language which had been made use of towards you, and which had been written respecting you, alleging that it was not only true in substance and in fact, but also that it was for the public good that your delinquencies should be made known. This matter came on to be tried before the learned Judge who presided in the Criminal Court at Manchester at the beginning of last year. Both

when you went before the Magistrates and had Mr. Ellis Lever committed for trial, and when you went into the witness-box upon the trial and were examined before the learned Judge, you knew as well as you know now that you had been guilty of the offences which are alleged against you. You knew that his justification, as he pleaded it, was perfectly true; and yet, knowing that he was an innocent man—that is to say, that there was no pretence for criminally prosecuting him for a libel—you went into the witness-box, and you swore that you had not, directly or indirectly, at any time received commissions. The question was put to you in various forms by your own learned Counsel, by the learned Counsel who appeared for Mr. Ellis Lever, and again by the learned Judge, in order that there might be no mistake. Three or four times over that question was, in substance, put to you; and three or four times over, with the knowledge that it was untrue, you answered, in substance, as I have already stated. What was the object of that perjury? The object of it was clear. It was, by false evidence, to exculpate yourself from the charges which had been made against you, and to clear your character, which you knew could not legally and honestly be cleared, of the imputations made against it. In order to do that, you did not hesitate to endeavour to have an innocent man fixed with a crime for which he might have been sent to imprisonment for a very long period. I should have been very glad if I could have found in this case, looking through the whole of it, that your misdeeds ended and terminated with the forgery of the letter by which you obtained these two sums by false pretences. Then I could have taken, with satisfaction to myself, a course which it seems to me impossible to take having regard to your later crime, which is that of endeavouring, by false swearing and by perjured testimony, to convict of a crime a man whom you knew to be innocent of it. That, I cannot help informing you, is a very serious and grave offence. It is a painful thing to hear, in the plain and simple, but striking language of your eloquent and learned Counsel to-day, of the ruin that this misconduct has brought upon you. You have been in a good position—a Justice of the Peace, esteemed by all who did not know of your delinquencies, an able man, a man of great shrewdness and of great ability—a man able by honest endeavours to raise himself to a position which might be envied by any man who sought to engage in such avocations as you were engaged in. But this matter has brought you to ruin; it has brought upon you the sad consequences which must attend the crimes which you have committed. It is always a painful thing for a Judge to have to inflict further misery upon those whose ruin has been already effected by their own misconduct, without any penalty coming from the law itself; but what am I to do? How many men stand in the position in which you stand for far less crimes—for crimes of embezzlement, for crimes of obtaining money under false pretences, for crimes of forgery of far less real seriousness—than that of which you are found guilty. What punishment do we award to them? Day by day men are sentenced to long terms of imprisonment, and even of penal servitude, for such crimes. By false pretences—I mean false pretences under such circumstances as you have been guilty of—men have over and over again been sentenced to long terms of imprisonment; and the result has been ruin to their families, their children have been left in beggary, destitution, grief, and trouble which it is impossible to describe in language; while one has been obliged, I will not say to turn a deaf ear, for no humane man can turn a deaf ear to such appeals. What would, however, be said if I were to make a distinction between your case and that of a man who had a much less honourable position to occupy—a man without your education and without your knowledge of that which is right and that which is wrong? It would be immediately said that I was administering the law differently in the case of a rich man to the way in which I should administer it in the case of a poor one. The state of your health is again a matter which I wish I could deal with; and I wish I could myself take it into consideration in awarding the sentence which I think it right to inflict upon you. But I know full well that during the period of your sentence you will be under the watchful eye and care of those who, knowing your condition, will be anxious not to cause you to undergo one single hour's pain, by reason of your physical suffering or condition, beyond that which you are able to bear, and which it would be fairly reasonable to abate. I also know this—that if, in the course of your confinement, it shall be thought necessary that other steps should be taken with a view of your release before the termination of your sentence, there is always an appeal which you can make to the Home Secretary to advise Her Majesty to remit a portion of the sentence which I am about to inflict upon you; and you may rely upon it, if necessity should arise for the making of such an application, you will not find any obstacle in me to the remission being granted to you if the Home Secretary should think fit, with my silence, to advise Her Majesty to remit it. I say this to you as an explanation and a reason why I cannot myself, under the circumstances before me, take into consideration the ill state of your health. The sentence which I am about to pronounce upon you is one which will date from the time of your conviction, and not from to-day. I am going to pass upon you one sentence which will be concurrent with others which I may have to pass upon you upon the other indictments which have been preferred against you. The sentence that I shall pronounce upon you will be on the charges of perjury; and upon these charges I feel I should be waiting in my duty if I did not pass upon you a sentence which I know will fall heavily upon you, but still not more heavily than I think the law requires it to fall. The sentence is for the crime of perjury, of a nature which I think was committed under most serious and aggravating circumstances. It was perjury committed not for the purpose of escaping from your pecuniary debt, but with the double object of escaping the imputations cast upon your character, and fixing an innocent man with your guilt. That is perjury of a very sad description. For that I feel it my stern duty to do that which I am very reluctant to do, and that is to pronounce upon you the sentence that you be kept in penal servitude for five years. With reference to the other charges in the other indictments, I shall direct the sentence to be entered upon each of those charges upon which you have been convicted, of one year's imprisonment with hard labour. These sentences will run concurrently with the term of penal servitude; that is to say, one year's hard labour upon each of the charges for false pretences which I have had before me. Upon the Common Law forgery there will be no hard labour.

The prisoner was then removed.

THE NEATH GAS-WORKS LOAN.—At the meeting of the Neath Town Council on Monday last week, a letter was read from the Local Government Board, sanctioning the loan of £1700 for gas-works purposes, if repaid in 30 instead of 50 years. The Council agreed to this modification.

BUXTON WATER SUPPLY.—The new reservoir which Mr. J. Hague, Assoc. M. Inst., C.E., of Buxton, has been for some time constructing for the storage of water for the supply of that town, has now been completed. It will contain 20 million gallons. It is lined with concrete 10 inches thick, upon which hard-burnt bricks are laid in a 3-inch coating of cement. About 1200 tons of cement were used; and 7200 tons of stony gravel and sand were employed for the concrete and brickwork.

Miscellaneous News.

THE ALLEGATIONS AS TO THE HALIFAX GAS COAL CONTRACTS.

The Monthly Meeting of the Halifax Town Council which was held last Wednesday, under the presidency of the Mayor (Alderman J. Booth), was attended by an unusual number of ratepayers, in anticipation of a discussion on certain allegations which have been made with reference to the coal contracts of the Corporation, as contained in the correspondence published in the JOURNAL last week. On the motion for the adoption of the minutes of the Gas Committee,

Aldermen RILEY (the Chairman of the Gas Committee) said: In moving these minutes, I beg to call the attention of the Council to paragraph one, as follows:—"Letters were read by the Chairman from Mr. Ellis Lever, of Colwyn Bay, North Wales, and Mr. Thomas Fox, of the Silkestone Coal Company, Barnsley, with reference to coal contracts." Other letters have been received since this time; and the whole of them have been printed by order of the Gas Committee. All that I have to say on the subject is this—that everything that has come to the knowledge of the Committee, or any person connected with the Gas Department, has been laid before you all. This consists of the articles in the *Pall Mall Gazette* and the letters of Mr. Lever and of Mr. Fox. These articles and letters have, no doubt, been greatly talked about, and the meaning of them misconstrued, and the importance of them greatly exaggerated. I suppose we shall always have persons among us who are so dishonest and corrupt themselves that they cannot possibly believe in the honesty and integrity of anybody else. These rumours, having once started, have increased in enormity as they passed from person to person, or as Pope says:

"The flying rumours gathered as they rolled,
Scarce any tale was sooner heard than told,
And all who told it added something new,
And all who heard it made enlargements too;
—In every ear it spread, on every tongue it grew."

In this manner has the scandal grown out of the articles and letters mentioned above. But the members of the Gas Committee and persons connected with the management of the works have at present nothing whatever to do with the imaginations and vague rumours of these idle tattlers and busybodies, but must confine themselves to the rebuttal of the actual imputations which have been made relating to the gas-works and their management, particularly in relation to the coal contracts. As yet these consist merely of ambiguous insinuations of corrupt practices. The *Pall Mall Gazette* says: "We should hear shortly of disclosures in Halifax, if the parties concerned dare to court inquiry." Mr. Levers says: "In the interest of fair and honourable trading, as also of the ratepayers and gas consumers of Halifax, I must ask you for an appointment to enable me to show you how the Committee have been dealt with in the past." Mr. Fox says (and here is the kernel of the whole of this matter: "I am informed, on very good authority, that one man has an interest, directly or indirectly, in many contracts with the Gas Department of the Corporation of Halifax; and it would be well that the matter should be sifted to the bottom. Halifax cannot desire a repetition of the Salford scandal." I will not weary you with reading through the whole of the articles and letters above referred to and the replies of the Town Clerk; nor is it necessary for me to do so, as they have all been printed and freely circulated, and I have no doubt you are all fully conversant with them. Let us see what these articles and letters come to. The Editor of the *Pall Mall Gazette*, on being asked by the Town Clerk whether the allegations which appeared in his paper meant to impart a distinct charge of corruption against the Gas Committee of the Halifax Corporation, or their servants, or both, and whether the article was a challenge to them to court inquiry, replies—taking refuge under the ambiguity of the words of the article—"that he is not prepared to become responsible for the construction which other persons or papers may have placed on a note published in the *Pall Mall Gazette*." The Town Clerk then replied to the Editor, saying that his letter seemed to "repudiate the construction put upon the words in the *Pall Mall Gazette* by the public and the press, and to shirk the responsibility attaching to the words used;" and also that the Corporation accepted the challenge contained in the article, and not only dared, but courted the fullest inquiry. The Town Clerk also informed the Editor of the *Pall Mall Gazette* that the Corporation would meet on the following Friday, and that he would be glad to know whether the remarks referred to any member of the Corporation, or their officials. But on these points, and to these queries, he has not received any reply. The Town Clerk wrote to Mr. Lever on the 24th of May last, saying that he would be glad to see him any time the next week between ten and five o'clock. But to this letter this gentleman—who has the interest of fair and honourable trading so much at heart, and with the information in his possession—has not even deigned a reply. Mr. Fox, on being several times written to by the Town Clerk, refuses to say whether the man referred to in his letter as being interested in contracts with the Gas Department is a member of the Town Council or a servant of the Corporation, or neither one nor the other; and also refuses to furnish any specific information unless indemnified against all costs in the event of the charges being proved. Of the nature of these charges, whether grave or trivial, he says nothing. If Mr. Fox, or any other person, will formulate a direct charge against any member of the Gas Committee, or against anyone connected with the management of the gas-works, then I for one—and I am sure I may say the same for every member of the Gas Committee—am fully prepared to meet and disprove the same. But as yet no one has dared to make such a charge; and therefore there is nothing for us to meet or disprove. I have to move—"That the minutes of the proceedings of the Gas Works Committee of the 1st and 15th of June last be approved and confirmed; that the correspondence between the Town Clerk, Mr. Ellis Lever, Mr. Thomas Fox, and the Editor of the *Pall Mall Gazette* be referred to the Mayor, Alderman Ramsden, and the Town Clerk, with instructions to lay the same before Counsel, and take such steps as they may be advised, and report to the Council; that Mr. Fox be informed forthwith that, if the person referred to in his letter of June 2 be a member of the Council or a servant of the Corporation, his offer to prove his charges, on being indemnified against cost, be accepted—it being understood that such charges shall be proved in a Court of Law."

Mr. J. BINNS (Deputy-Chairman of the Committee) seconded the motion, and said that everything which had been done by the Committee had been done openly and above-board. The Council might rely upon it that the eyes of the Committee had not been closed; and he could truly say that nothing had come to their knowledge which could compromise either the members of the Committee or the servants of the Corporation. They would be perfectly ready to hear all that any gentleman might have to say concerning the subject. The Committee thoroughly disapproved of anything in the nature of commissions and of corruption of every kind; and they challenged anyone to make whatever statements could be made against the Committee. The position was rather an alarming one, and it must be met. The ratepayers had become somewhat excited about it.

Perhaps the members of the Gas Committee, out of their perfect innocence, had been cool by contrast. He begged the ratepayers, however, to withhold their judgment until such time as the Council could legally investigate the matter. Their friends would give them credit for the best intentions. The Committee did not know of any corruption, and were willing to hear of any that might be known outside the Committee.

Mr. J. BROOK, after describing his thorough knowledge of the affairs of the Gas Committee, said he had very great pleasure in supporting the resolution.

Alderman RAMSDEN remarked that, while he was not disposed to shirk any duty that might be put upon him by the Council, he rather doubted the wisdom of the second clause of the resolution, referring to Mr. Fox. Whatever happened, someone would have to pay, while Mr. Fox would not be under any pecuniary responsibility whatever. He doubted whether they had the power to spend public money in finding an indemnity for Mr. Fox under these circumstances. He took it that the duty of himself and his colleagues who were mentioned in the resolution was as to the first part only, and not the second.

The MAYOR: That is understood. The Town Clerk will answer the point as to our being able to take action.

The TOWN CLERK said he should not have drawn the resolution if he had not thoroughly made up his mind that the Council had power one way or the other. If Mr. Fox's charges were proved in a Court of Law, the resolution would indemnify him from all costs. But if he failed to prove his charges, he would have to pay his own costs and those of the Council as well; and he would also be subject to other inconveniences which need not at present be mentioned.

Mr. JESSOP said the question was causing a great deal of excitement among the ratepayers—excitement which had assumed such proportions that he questioned whether the resolution would satisfy them. He therefore wished to move an amendment—not from any disrespect to the gentlemen named, and not doubting that they would investigate the matter without bias, but desiring that the public mind should be relieved from any doubt. If the question was to be relegated to a Committee of Inquiry—

The MAYOR said it was not a Committee of Inquiry. It was simply sought to take Counsel's opinion, and to report to the Town Council.

Mr. JESSOP: Then, is not the Committee to receive evidence?

The MAYOR: Certainly not.

Mr. MINGLEY urged that it was due to the members of the Gas Committee that they should be regarded as perfectly innocent in this matter; and every honest-minded man would, he said, have this feeling towards them.

Mr. BROADBENT said every one had the fullest confidence in the Committee; but it was clearly the duty of the Council to adopt the resolution. These rumours were not new; and it must be painful to members of any Committee to hear such remarks. Therefore it was high time that the rumours should be silenced once and for all. If Mr. Lever and Mr. Fox were not prepared to come forward, they were unworthy of notice. If, on the other hand, they had anything to say, let them have every facility for saying it.

Mr. OAKES was of opinion that the scandal had arisen out of the dis-appointment of some person who did not get a share of the contracts. He said the Council had the utmost confidence in the Committee; and it was scandalous that such rumours should be set afloat.

Mr. JESSOP asked if it was true that the Committee had given Mr. Ellis Lever 9d. per ton more for cannel coal than the figure for which the Crosland Moor Company had offered to supply it.

Alderman RILEY said the Crosland Moor Company's tender was exactly 9d. per ton less than Mr. Lever's for the same kind of coal.

Mr. BIRSTOW: Mr. Lever never had the contract at all.

Mr. BINNS: And never has had.

Alderman D. SMITH thought it was folly to go to law over the subject. He would not spend 6d. on it.

Alderman POLLARD differed, and was of opinion that the Council ought to court the fullest inquiry.

The MAYOR said people were too ready to spread rumours of the kind in question. There was no other course left for the Corporation to take than to prosecute the inquiry to the bottom. Though the charges were so indefinite and intangible that it was difficult to say what they meant, there were charges; and it was their duty to meet them. If there had been a regular system of speculation, or if a large amount of money had been abstracted, could the Halifax Corporation have produced gas at a price lower than that charged in any other town in the country, or show so much profit? On the face of it, the rumour was a vile slander. Whatever the Council might do, he would take good care that the matter was investigated; and if there was a possibility of "warming" the perpetrators, he would warm them, either through their jackets or their purses. These things should not be allowed to go on with impunity.

The resolution was then carried unanimously.

The following letter, dated the 5th inst., addressed by Mr. Ellis Lever to the Town Clerk of Halifax, was received by the latter last Friday:—"Dear Sir,—My attention has been called to the fact that the letter which I wrote to you on the 22nd of May last has been published in the newspapers without any notice of such publication being given to me. The letter was of a confidential character, although not marked private; and I am very much surprised to find that it has been handed to the press. It was not my intention to make any imputation against the Gas Committee or the officials of the Corporation, all of whom are unknown to me. A sudden death in my family and absence from home have prevented my seeing you, as I had intended."

NEW JOINT-STOCK COMPANIES.—The following joint-stock companies have lately been registered:—The Long Melford Gas and Coal Company, Limited, with a capital of £4000, in £1 shares, to purchase or otherwise acquire the whole, or part of the business properties, consisting of the gas-works and coal-yards, situate at Long Melford, in Suffolk, as a going concern, from the present owner (Mr. A. Stuart).—The Buckingham Electric Light and Power Supply Company, Limited, with a capital of £5000, in £1 shares, to carry on at Buckingham and elsewhere in the county of Buckingham, the business of an electric light and power supply company in all its branches.—The Electrical Purification Association, Limited, with a capital of £15,000, in £1 shares, to acquire certain patents relating to "improved means of oxidizing and decomposing by electrical action organic matter and inorganic salts in sewage water and other liquids, and the production of certain products therefrom, and improvements in the means or appliances for treating sewage by electrolytic action, and for the disposing of the deposits thereof." Among the first subscribers are Mr. W. Webster, electrician, who agrees to take 200 shares, and Mr. T. Slater, who is down for 1000 shares.—The Tenbury Union Gas Company, Limited, with a capital of £3000, in £5 shares, to light with gas or other lighting power the town of Tenbury, in the county of Worcester. The Company is registered without Articles of Association.

BIRMINGHAM CORPORATION GAS SUPPLY.

THE LIGHTING OF COURTS.

At the Meeting of the Birmingham Town Council last Tuesday—the Mayor (Alderman Pollack) in the chair—the report of the Gas Committee, the principal portions of which were given in the JOURNAL last week, was to have been discussed; but, owing to the length of the proceedings on other matters on the paper of business, it had to stand over till the next meeting. The subject of the lighting of courts, however, came under consideration, on the presentation of the report of the General Purposes Committee containing the following remarks thereon:—“In reference to the instruction given to the Committee ‘to take into consideration the question of the compulsory lighting of courts, terraces, common stairs, and other private ways in the borough, and to take such steps as they might deem expedient to obtain powers to enforce such lighting, and to report,’ the Town Clerk cites a recent decision as to what constitutes a street within the meaning of the Public Health Act, and quotes a clause from the Burgh Police and Health (Scotland) Bill now before Parliament, proposing to compel owners of court property to place lamps in courts and alleys. The Town Clerk sums up the case: ‘Starting with the proposition that courts in towns are objectionable on sanitary grounds, that their extension is discouraged by the Local Government Board, that the houses in them are rated (*inter alia*) for public lighting, and that the surface of the courts can be treated as a private street at the will of the Local Authority, it does not appear to me that such a clause as that contained in the Scotch Bill would be consistent with the general law of this country.’”

The Mayor, in moving the adoption of the report, said no one would deny that the time had now arrived when this matter should be settled. It had been previously stated in a report by the Town Clerk that the Council had power to declare courts and terraces private streets; and this was confirmed by a recent legal decision. If this power were exercised, it would entail upon the Corporation the necessity of lighting the courts and terraces at the public expense; but it would at the same time entail upon the owners of the property very considerable expense in carrying out the necessary works, and would deprive them of all interest in so much of the land as should be declared to be a highway. The Town Clerk did not think that any special legislation in the nature of the Scotch Bill now before Parliament with a view to making it compulsory upon owners to light their courts could be obtained in England; the law already being sufficient to deal with the matter. But the Public Works Committee had offered the owners every facility for undertaking the work in the shape of reduced rates for the gas supply and other concessions, which would be far cheaper to the owners than if they drove the Council to exercise their powers to the full. It only remained to be seen whether the landlords of the courts would show so much common sense as to consult their own interests by undertaking to light their courts. In the event of the Corporation being driven to enforce their powers, the burden of the expenditure would fall upon the ratepayers.

Sir T. MARTINEAU seconded the motion; and it was declared to be carried.

Mr. GRANGER complained that the vote had been taken without an opportunity being afforded him of speaking.

The Mayor explained that, after the motion had been seconded, he looked round the Chamber, but did not observe anyone desirous of speaking. He should, however, give Mr. Granger an opportunity of doing so.

Mr. GRANGER said he thought it was to the interests of the social and moral condition of the people that the courts and terraces should be properly lighted. There were upwards of 6000 courts in Birmingham; and yet not more than 150 of them were lighted. It was evident that moral suasion would not have the desired effect upon the property owners; and he considered that other means would have to be tried.

Mr. BRINSLEY thought there were two sides to the question, and that some of the small property owners were not in a position to undertake the lighting of the courts.

Upon a vote being taken, the report was adopted.

PARA GAS COMPANY, LIMITED.

In view of the general meeting of this Company to be held next Thursday, the report of the Directors, with the accounts for the half year ending March 31 last has been issued. It states that the revenue for the six months is slightly in excess of that earned during the previous half year, but somewhat less than that of the corresponding period of 1886-7. The expenditure has been considerably reduced in some of the most important items; and the result is a profit of £8427 on the half-year's working. The Directors have deducted from the gas-fitting plant account £2000 of the amount standing in the gas-fitting rental reserve account, and have written off a further amount of £1000 for depreciation. Mr. R. Hall (formerly Assistant Manager), who took full charge as Manager on the 2nd of August last, retired from his appointment at the expiration of his agreement, having been three years resident in Pará in the service of the Company; and Mr. John Gibson Newbigging has been appointed Manager and Engineer in his place. The petition to the Imperial authorities in Rio, alluded to in the last report, was referred to the Provincial Government “for information;” and this and other formalities caused such delay, that no definite reply had been received up to the date of Mr. Hall's departure. The repayment of duties had, however, received the attention of the Imperial Government; and a speedy settlement of this question is anticipated. The late Manager reports the works and property of the Company in good condition. The Directors regret to have again to draw the attention of the shareholders to the treatment they are receiving at the hands of the Provincial Government. Fines on the public lighting amounting to £600 for the half year have been inflicted, notwithstanding the efficient discharge of its obligations by the Company. The Directors recommend the payment of dividends for the half year at the rate of 4 per cent. per annum upon the ordinary stock of the Company, free of income-tax; and 7 per cent. per annum upon the preference shares, less income-tax.

LINCOLN CORPORATION GAS SUPPLY.

THE CHARGES FOR THE HIRE OF SMALL METERS.

At the Meeting of the Lincoln Town Council last Tuesday, Alderman Maltby moved, pursuant to notice—“That it be an instruction to the Gas Committee of the Corporation that they take into consideration the desirability of reducing the charge for meters rented by consumers having three lights and under.” He said when the question of the purchase of the gas undertaking was broached, an inducement was held out that it was hoped one of the first reductions that would be made would be in the charge for the hire of small meters. He had been at the trouble to obtain some information on the subject; and he found that if they did not take into consideration the inspecting and watering, in 16 years, at 4s. per year, a meter was paid for twice over. This was not the case with the larger meters. If the charge on the 3-light meters was reduced to 6d. per quarter, there would be an annual loss of £380; but he was fully satisfied that this sum would be made up in the increased consumption of gas. He was informed that there had been a large number of meters returned of late;

the greater proportion of which were 3-light meters. This fact spoke of there being some dissatisfaction with the charges. In many cases, where little gas was consumed during the summer months, the charge for the meters was out of proportion to the charges for the gas consumed. He felt assured that the reduction he advocated would result in additional meters being required and more gas consumed. Mr. Ward, in seconding the motion, said that probably in the whole history of the gas undertaking they had never attained such a degree of prosperity as at the present time. The consumers therefore ought to have some advantage, and to his mind the poorer classes should have it. At present in many cases the rental of meters amounted to more than the charge for the gas consumed. Mr. Cannon had no objection to the proposition; but he maintained that it was, on the whole, an unnecessary one. It was understood that some change would probably be made when the accounts of the gas undertaking were before them, and those accounts were now being handed round. He hoped the reduction would refer to all the gas-meters. This was the proposition he was prepared to put before the Gas Committee; and it would only make a further difference of £120. Mr. Wyatt was in favour of sweeping away the rents of the meters altogether; and if it was found necessary, to “make both ends meet,” they could charge more for the gas. The Mayor (Mr. T. Martin) reminded the Council that when the payments were made to the sinking fund last year, they were £8 short; and until now they had not had any money in hand. Supposing the price of coal went up during the next twelve months, they might be in an awkward position if they relieved the gas consumers of this meter-rent. The motion was then put and carried.

WIDNES LOCAL BOARD GAS AND WATER SUPPLY.

ANNUAL INSPECTION OF THE GAS AND WATER WORKS.

The annual inspection of the Widnes Gas and Water Works by the members of the Local Board took place on Tuesday, the 26th ult. It commenced at the gas-works, where the party were met by the Gas and Water Engineer (Mr. Isaac Carr), who conducted them through the works, and explained the method of making gas. Special interest was manifested in the Dinsmore process of gas manufacture from coal tar, which had been adopted at these works; the apparatus being now in course of erection. After making a thorough inspection of the gas-works, the party drove to the covered water reservoirs of the Board. The large reservoir, which was opened ten years ago, was illuminated, by the direction of Mr. Carr, with 600 candles; and the effect was most charming. The water had been previously drawn off, in order that the members might inspect the structure, to ascertain how the masonry had stood. It was found to be in excellent preservation. This is the first time the reservoir (which at the time of its construction, was the largest in the world) has been emptied; the layer of sand, after so long a period of pumping, was in no part more than three-quarters of an inch in depth—a fact which goes to prove the excellence of the water received from the source and supplied to the town. The reservoir is 330 feet long, 240 feet wide, and 23 feet high, and its storage capacity is 11½ million gallons, which is just sufficient to provide Widnes with six days' supply. The roof of the reservoir is supported by 360 massive stone pillars. The reservoir has been cut out of the solid rock, and was constructed at a cost of £30,000. During the past year the Board were able to pump a larger quantity of water than previously, owing to the improved engines which have been put up. There is now sufficient water for all purposes, and to spare; and an extra million gallons per day could be pumped, should necessity arise. The party next visited the pumping station at Stocks Well, where they inspected the new engines, which, it was stated, were pumping out of the well 1½ million gallons of water per diem. The members then drove to the Netherly pumping station, where, however, there is nothing new since the last visit, twelve months ago. Here 1,400,000 gallons of water are daily pumped. The party then returned to Widnes; expressing great satisfaction at the way both the gas and the water works are managed by Mr. Carr.

THE POTTERIES UNDERTAKING OF THE BRITISH GASLIGHT COMPANY.

THE ALTERATIONS IN THE COMPANY'S ACCOUNTS.

At the last Meeting of the Hauley Town Council—the Mayor (Mr. H. Palmer) presiding—the minutes presented by the Gas Sub-Committee contained the following resolution which had been passed:—“The Sub-Committee having considered the letter from the Board of Trade as to the British Gaslight Company's form of accounts, and the other correspondence, reports that it sees no reason to withdraw from its contention that the amounts previously charged for depreciation and insurance by the Company should be brought into account, and refunded in that manner to the consumers, and that the accounts should be altered in accordance with the letter sent to the Board of Trade by the Town Clerk on Dec. 21, 1887; and also that this Sub-Committee feels that, but for the untimely publication of certain correspondence relative to the matter, no change would have taken place in the views of the Directors of the Gas Company, as explained in their letter of the 1st of December last.”

Mr. BEBBINGTON referred to the fact that the resolution of the Gas Sub-Committee contained a minute to the effect that, but for the untimely publication of certain correspondence, “no change would have taken place in the views of the Directors of the Gas Company.” This could not be true. He asked how could the disclosures in the letters referred to possibly affect the Company? The latter were in possession of the information. He did not feel any regret for the publication of the letters; and he must contend that the Sub-Committee of the Corporation, in keeping it in its possession, away from the knowledge of the Council, over two Council meetings an important letter, had done an improper and an irregular thing. He then proceeded to discuss the question of charging for depreciation, and said the Company had never stated that they had the power to charge for depreciation, but the people of Hanley had forced it on the Company. He contended that a more thorough and searching investigation was required than the Council had at present made; and he was of opinion that it would be wise and right that the clause referred to in the report of the Gas Sub-Committee should go back for further consideration. He concluded by moving an amendment to this effect.

Mr. BRADFORD seconded the amendment.

Mr. HAMMERSLEY, in an exhaustive speech, proceeded to defend the action of the Corporation in their recent litigation against the Gas Company, and also the resolution passed by the Gas Sub-Committee. After an able criticism of the Gas Company's accounts, he said the thanks of the community were due to those members who had done so much for the benefit of the inhabitants of the town. According to the Company's own statement of accounts, one-seventh of the revenue would be kept in the pockets of the tradesmen and others in the town, owing to the action of the Sub-Committee, instead of going to swell the Company's dividend.

Alderman POWELL also offered some remarks in justification of what the Gas Sub-Committee had done. It would be in the memory of the Council how rejoiced they were on the receipt of the letter of the 1st of December, and how delighted that they had obtained the one thing they had been fighting for. He suggested that the Directors of the Company, in consequence of what had recently taken place, had arrived at the

conclusion that there was not now the same disposition in the Council Chamber that there was in times past, and that therefore they were not going to do the thing they said they were going to do on the 1st of December last. The Council had not received any indication until the present month that the Directors had changed their minds. On the contrary, they were all clearly under the assurance that the Directors had ordered to be written what they intended should be done. His own conviction was that if certain correspondence had not been published, the position taken up by the Directors would never have changed.

Alderman POWELL contended that not a single act of the Gas Sub-Committee had been done in a hole-and-corner manner. Indeed, every act of that Committee had been reported to the General Purposes Committee, and afterwards submitted to, and approved by the Council; and now Mr. Bebbington wished to censure the Council.

Mr. BRADFORD submitted that the same result which had been obtained might have been secured by the adoption of more pleasant means, and without litigation.

On a vote being taken, the amendment was lost, and the minutes of the General Purposes Committee, including those of the Gas Sub-Committee, were approved.

Two notices of motion which Mr. Bebbington had placed upon the agenda paper were not proceeded with; the members rising in a body on the completion of the ordinary business. These motions were as follows:—“(1) That this Council hereby declares its approval of the proposal of the British Gaslight Company, Limited, to the effect that they are prepared to discontinue the charges on account of insurance and depreciation. (2) That in the opinion of this Council it is desirable and necessary for the good government of the borough that all such proposals as would involve the borough in obligations, or would directly entail an expenditure exceeding £20 be submitted to and receive the sanction of the Council before action be taken upon them.”

Mr. BEBBINGTON intimated that he should place the notices on the agenda for consideration at the next meeting.

BANGOR CORPORATION GAS SUPPLY.

THE PAST YEAR'S WORKING.

According to the report of the Gas Engineer of the Bangor Corporation (Mr. J. Smith) on the working of the gas undertaking in the year ending March 25, 1888, which he has lately presented to the Gas and Water Committee, there was a falling off to the extent of 629,000 cubic feet in the quantity of gas used, as compared with the previous financial year. Only 200,000 cubic feet of this were, however, in respect of the private consumption; the remainder being due to the public lamps being lighted for a fewer number of hours. The unaccounted-for gas was less by 179,900 cubic feet, and the make per ton of coal more by 427 cubic feet than in 1886-7. There was an increase in the item of repairs to plant; 15 retorts having been renewed, and a number of meters altered to M. Wybauw's arrangement. The former cost £78, and the latter £50, against which there was £66 additional income on residuals, rent of stoves, &c. Sulphate of ammonia produced £99 net, as against £63 in the previous year. The total revenue from gas was £3886, or £258 less than before; £107 4s. 6d. being due to the curtailment in the public lighting. But the gross profit, by reason of the increased income from residuals, &c., was only £219 less than in the year 1886-7. The quantity of gas used for purposes other than lighting increased considerably; being during the three last quarters 590,600 cubic feet more than last year, in consequence of the reduction in price made in June, 1887, to 2s. 6d. for day gas and 5s. for night gas. Although there was a loss of £34 10s. 9d. on the gas used in the daytime, the profit on the increased consumption amounted to £34 2s.; leaving the net loss on the experiment only 8s. 9d. There were fixed during the year 19 cooking-ranges; also gas-fires and other apparatus for using gas. Mr. Smith says it appears by the quantity of gas sent out up to the present time, that the consumption of gas this year will be considerably more than in any previous year. In the 12 weeks preceding June 22 last (the date of the report) he sent out 249,800 cubic feet more than last year, and 157,800 cubic feet more than in any previous year; and if the illuminating power is kept up without increasing the expenditure too much, the present will, he says, be a prosperous year for the undertaking. The following are the general results of the year's working:—

Coal carbonized—	
Common, 1056½ tons	1794 tons.
Cannel, 187½ „	7 6
Percentage of cannel used	17,599,500 cubic feet.
Gas made	9,810 „
Do. per ton of coal	15,950,200 „
Gas sold	90 62 per cent.
Do. per cent. on make	866,900 cubic feet.
Gas used in cookers, engines, &c., at 2s. 6d. per 1000 feet.	165,700 „
Gas used on works	0 94 per cent.
Do. per cent. on make	16,115,900 cubic feet.
Gas accounted for	91 57 per cent.
Do. per cent. on make	1,483,600 cubic feet.
Gas unaccounted for	8 43 per cent.
Do. per cent. on make	112½ tons.
Coke made	12½ cwt.
Do. per ton of coal	5½ „
Do. used per ton of coal	7½ „
Do. sold	57 7 per cent.
Do. sold, per cent. on make	s. d.
Cost of coal per ton, less residuals	8 5½
Cost of gas in holder, less residuals	1 7 per 1000.
Amount of capital employed	£ s. d.
Do. per ton of coal carbonized	27,660 10 3
Do. per 1000 feet of gas made	15 8 3
Do. per 1000 feet of gas sold	1 11 5
Do. per 1000 feet of gas sold	1 14 8
Illuminating power of gas required by Act	14 candles.
Illuminating power supplied	17 „
Average price of coke sold	s. d.
	9 10 per ton.

The capital expended on the works amounts to £27,660 10s. 3d.; but there is also a sum £16,614 6s. 6d. premium to be paid on redemption of annuities—making the total amount to be provided by the sinking fund on account of gas-works, £44,274 16s. 9d.

THE NORTHERN COAL TRADE.—There is a better demand for steam coals in the North; and prices are so firm that in one or two instances there is now asked the rate of 8s. 6d. per ton, free on board in the Tyne, for best qualities. It is not known to have been paid, however; and generally from 7s. 6d. to 7s. 9d. net is the rate for this quality, whilst second-class coals may be put at about 7s. In gas coals there is already a rather improved demand; but the price is no better. Some discussion has taken place in local coal trade circles as to the wisdom or otherwise of collieries which have accepted the great London gas coal contracts for three years to come, during which many experienced in the trade believe that a sharp increase in prices is probable. The demand for gas coal for export continues good. Household coal is extremely dull just now; the demand being about at the minimum, and the price very weak, whilst the competition is great. In the coke trade there is an active demand generally.

WARRINGTON CORPORATION GAS SUPPLY.

THE MANAGEMENT OF THE GAS-WORKS.

On Monday last week a largely-attended meeting of ratepayers was held at Warrington to protest against the proposals of the Gas Committee relative to the appointments and salaries of officials, to which reference has been made in our columns. Mr. H. Thornton moved a resolution disapproving the proposals, and calling for an investigation into the management of the works, for a reduction in the price of gas to the consumers, and for quarterly instead of half-yearly accounts. Mr. Knean seconded the resolution. Mr. Barlow moved, and Mr. Woods seconded, an amendment, expressing confidence in the Committee. Both gentlemen met with constant interruption; and the resolution was carried by an overwhelming majority.

At the meeting of the Town Council on the following day, an animated discussion took place on the report of the Gas Committee embodying the above-mentioned proposals as to the appointments. Alderman Holmes, as Chairman of the Committee, referred to the resignation, through failing health, of Mr. J. Paterson, and the proposal to retain his services as Consulting Engineer at a salary of £100 per annum. He would report at least once a month on the condition of the works. They proposed to appoint Mr. William Spence Haddock (who had served his articles under Mr. Paterson), and pay him a salary of £300 per annum. Mr. Platt proposed that Mr. Paterson be not appointed Consulting Engineer. Mr. Pierpoint seconded the amendment. Ald. Webster seconded the motion for the confirmation of the minutes. He said that not a single farthing was contributed to the gas-works by the borough, but, on the contrary, the works had contributed largely to the reduction of the rates. The expenses of the Gas Department, as to salaries, had been £1248; but the proposed rearrangement would result in a saving of £200 a year to the Committee. As to the price of gas, since the works came into the possession of the Corporation there had been two reductions. Mr. Roberts denied that the rates had been reduced out of the profits of the gas-works; and he strongly condemned the principle of dual control. Mr. Monks supported the proposals; and denied that there would be any dual control. If the Gas Department did not contribute to the reduction of the rates out of the profits, the debt on the works was reduced from that source. Alderman Davies appealed to the Committee to modify the proposals by appointing Mr. Paterson as Consulting Engineer at £100 for one year only. Alderman Harrison approved this suggestion. The Committee had, he said, taken credit for saving £200 a year by the reorganization of the Gas Department; and he urged them to save £300 by abandoning one of their recommendations. On the amendment being put, it was lost; 14 votes being for, and 17 against it. Alderman Davies moved that the minutes be confirmed, with the exception of that relating to the appointment of Mr. Paterson as Consulting Engineer, and that he be appointed for one year only. The Mayor (Alderman Sutton) said the amendment as it stood could not be legally carried. Alderman Davies amended the resolution; retaining the first part, and concluding “that the Committee be recommended to submit an amended report to restrict the engagement for one year.” The amendment was carried.

GALASHIELS GAS COMPANY.

The Fifty-fourth Annual Meeting of this Company was held last Tuesday—Mr. J. Aird, Chairman of the Company, presiding. The report of the Directors for the past year stated that the quantity of gas manufactured was 52,968,300 cubic feet, and that the loss by leakage was 1,916,834 cubic feet; being equal to 3 61 per cent.—certainly a very low rate. In the works and offices the amount used was 500,000 cubic feet; so that the quantity of gas passing through the consumers' meters for the year was 50,551,466 cubic feet, as against 49,259,390 cubic feet in the year 1886-7; thus showing an increase for the year of 1,292,676 cubic feet. The report stated that the illuminating power of the gas had been maintained during that year at the usual high standard; and also (as mentioned in last week's JOURNAL) that the price of gas for the year 1888-9 had been reduced to 2s. 11d. per 1000 cubic feet. All the works were reported to be in good repair. The Directors regretted to have to report the death during the year of Mr. W. Haldane, who had ably and efficiently discharged the duties of Secretary and Treasurer for upwards of 30 years. In his place they had appointed Mr. J. Pike. The balance-sheet showed that the assets, after making allowance of 2½ per cent. for depreciation, rated the value of the works at £23,539 2s. 4d.; in addition to which there was the June collection, now due with recoverable arrears which together amounted to £1950. There was also in the bank the sum of £2293 2s. 10d.; and the stocks of various kinds brought up the total amount to £28,324 12s. 11d. In the shape of liabilities, there was the share capital (2100 shares at £10 each), amounting to £21,000; there was also the dividend of 10 per cent. recommended by the Directors; and, lastly, a balance of £5244 12s. 11d. to be carried to next account. The year's profits amounted to £2415 13s. 3d.; and the balance from last year's account was £4908 19s. 8d. The total income for the past year was set down at £8915 7s. 7d., and the expenditure amounted to £6499 14s. 4d.; the year's profits, as already mentioned, being £2415 13s. 3d. The report having been placed before the meeting, Mr. Fairgrieve moved its adoption. Provost Hall seconded the motion, and it was carried. Provost Hall and Messrs. Fairgrieve, Sanderson, and James Dickson were appointed Directors, in room of those who were retiring and were ineligible for re-election, to whom the thanks of the shareholders were accorded. The thanks of the meeting were also given to Mr. A. Scott, the Manager, for the way in which he had conducted the affairs of the Company.

THE WATER SUPPLY OF STAINLAND.—A Company is in course of formation to supply water to Stainland and the district from the Dean Head reservoir. The reservoir, which was originally constructed for the supply of water to mills in the locality has a capacity of 78 million gallons. The Oldham Corporation made overtures for the purchase of it some time ago; but the local opposition proved too strong for them before the Parliamentary Committee.

THE SALFORD CORPORATION GAS UNDERTAKING.—At the meeting of the Salford Town Council last Wednesday, the minutes presented by the Gas Committee stated that the profits on the gas undertaking for the year ended the 25th of March last amounted to £20,894. In reply to Alderman C. Makinson and other members, Mr. H. Lord, Chairman of the Gas Committee, said a number of men had been recently discharged from the gas-works; but it was not true, as asserted, that other men had been engaged to take their places. The men had been discharged because their services were not required. If the price of gas was to be reduced, a beginning must be made somewhere with the work of economizing. Mr. F. W. Roe-Rycroft asked whether the former Gas Manager had made any restitution; and if so, to what amount. The Mayor (Alderman Dickens) replied that the question was one that could not be rightly put to the Council at that moment; and therefore he declined to say anything on the matter. Mr. Rycroft proceeded to put other questions on the subject; but without effect.

PLYMOUTH GAS COMPANY.

THE SECRET OF THE COMPANY'S SUCCESS.

At the Annual General Meeting of this Company—briefly noticed last week—the Chairman (Mr. G. Henderson), when moving the adoption of the report, said he had no doubt the shareholders would consider the working results of the past year satisfactory; leaving as they did a balance of £10,426, compared with £10,471 the previous year—showing a difference of only about £50. In accordance with the hope he expressed at the previous meeting, the price of gas was reduced at Michaelmas last to 1s. 9d. per 1000 feet; and he believed that he was justified in saying that this was the lowest price charged by any gas company in the United Kingdom. It was possible that some gentleman present might be disposed to ask how it was that they were able to do this, especially when their long distance from the coal-pits was taken into account; for they had to obtain coals from Newcastle or Glasgow, and the cost of freight during the last year amounted to no less than £10,000. The reason they were able to do it was that in the early history of the Company for many years, instead of paying the maximum dividends of 10 per cent., the shareholders received 6 per cent., and the surplus profits were laid out in extending and enlarging the works; while subsequently, from time to time, they had appropriated large sums out of profits for depreciation and the renewal of plant. They now only required about 4½d. per 1000 cubic feet to pay their dividends. They had no borrowed capital; and consequently had an advantage over most other companies, which required from 1s. to 1s. 3d. per 1000 feet to do the same thing. This showed very plainly how it was that they were able to supply gas at such a low price; and, in fact, their capital was the lowest of any gas company in the United Kingdom. Their company was started as a consumers' company; and from the formation up to the present time, the Directors had always adhered to the policy of supplying gas at the lowest possible rates consistent with being able to pay their dividends. The reduction in the price of gas by 1d. per 1000 feet was a benefit of £1236 to the consumers; while the additional quarter per cent., which the shareholders were entitled to receive in consequence of the reduction, only amounted to £118. The revenue account however, in spite of the reduction in price, showed that the total amount received from the sale of gas was £43,623, as compared with £42,606 in the preceding year, or an increase of about £1000. Meter-rental advanced about £100. As to residual products, the sale of coke showed an increase of £600 or £700; while there was a rise of about £600 in the sale of sulphate of ammonia. The entire receipts for residual products were £13,239, against £17,909 in 1886-7. The total receipts of the year amounted to £60,666, or an advance of about £2500, notwithstanding the reduction in price. With increased revenue more coals and more labour were required in various ways in the manufacture of gas; and the total cost for coals, salaries, wages, and machinery was £40,553, against £38,953 before. During last year they laid down three miles of mains, extended mains into the suburbs, and took up some old pipes, which they replaced by larger ones; and all this had been paid out of revenue. The total expenditure was £50,239—an increase of about £2000. The quantity of coal carbonized during the year was nearly 47,000 tons—an average of something like 900 tons a week. The gas produced was 507 million cubic feet, against 484 millions in 1886-7. They were about to erect a new retort-house and some additional coal-stores; and contracts having been entered into, they hoped to get the buildings up before the end of the year, and have everything complete for the manufacture of gas during next year. It was well that they should anticipate the requirements of an increasing supply without being too closely driven; for the Directors intended to continue the policy which had guided them from the commencement of the undertaking—viz., to keep down the expenditure, and carefully watch the cost of production, so as to be able to continue to supply gas at the exceedingly low price of 1s. 9d. per 1000 cubic feet. Perhaps it was rather premature, but they might hope at some distant period to make a further reduction. As already announced, the report was adopted; and dividends at the rates of 12½ and 9½ per cent. per annum were declared.

SEWAGE POLLUTION OF THE THAMES.—The Chertsey Rural Sanitary Authority were last Wednesday, at the Chertsey Petty Sessions, fined £50 and £10 10s. costs for suffering polluted matter to flow into a tributary of the Thames at Chertsey, and £5 in respect of a similar offence committed at Addlestone.

ANOTHER WAY TO DISPOSE OF GAS PROFITS.—At the last meeting of the Belfast Town Council, on Alderman Sir John Preston moving the adoption of the report of the Gas Committee (consisting chiefly of accounts), Mr. Finuigan asked the Town Clerk whether a portion of the funds of the Committee could be allocated to the furtherance of a public duty. They were sorry that when the Channel Fleet were in the lough no entertainment was given by the Corporation, while another body entertained the officers. He thought the Corporation should have power to allocate certain portions of the surplus gas funds for the entertainment of distinguished visitors. The Town Clerk replied that there was no power to do this. The Act enabled the surplus to be applied for public purposes; but this meant purposes on which the Corporation were expressly authorized by other Acts of Parliament to spend money. Mr. Finuigan asked whether it would do if the Council passed a resolution declaring any particular thing a public purpose. The Town Clerk said it would not. The Mayor (Sir J. W. Haslett, J.P.) remarked that it was a desperate thing to bring up such a matter as this on a report of the Gas Committee.

THE GAS SUPPLY OF LEEDS.—In the course of the first of a series of articles in the *Leeds Mercury*, entitled "How Leeds is Lighted," the following particulars are given:—"Leeds was first lighted with gas in 1819. Oil gas was used in 1824; but this experiment proved a financial failure. Right on through the years the production of gas in the borough grew apace until, in 1870, the quantity made for the year amounted to 850 million cubic feet. For the year ending June, 1879, gas manufacture rose to a total of 1250 million cubic feet, which shows an enormous advance on the production achieved in previous years. The price charged for gas in the borough from 1870 to 1874 was 3s. 6d. per 1000 cubic feet; in 1875-6 a charge of 3s. 9d. per 1000 feet was made; in 1877 there was a decline in the price amounting to 3d. per 1000 feet; in 1880, 2s. 2d. per 1000 feet was the price, but a discount of 2½ per cent. was allowed, and at the present time the price is 1s. 10d. At the date last mentioned there were three gas-works in operation within the borough, and 1552 retorts in use. During this year 350 retorts have been added to the Nov Wortley works; making a total for Wortley alone of 780 retorts. The maximum daily production in 1880 was reached on Jan. 7 of that year, when 6,200,000 cubic feet were produced; and on the same day 7,564,000 cubic feet were sent out. During the comparatively short space of seven years, the production has been nearly doubled. In 1880 the length of mains in the district served by the system was upwards of 500 miles; the district embracing an area of 35 square miles. To-day there are calculated to be within the municipal and parliamentary boundaries 687 miles of piping in an area of 47 square miles."

NOTES FROM SCOTLAND.

(FROM OUR EDINBURGH CORRESPONDENT.)

EDINBURGH, Saturday.

The settlement of the main questions connected with the Edinburgh and Leith gas transfer has given the utmost satisfaction to the citizens—a circumstance which there is the more pleasure in recording because of the fear in some minds that the opposition would seize upon the moment of the completion of the agreement to try and inflame the public mind. The fear was all along groundless, unless upon the assumption that a ridiculously bad bargain was to be made, which was not to be expected, and which, it is almost needless to say, has not resulted, but the very opposite. The measure came before the House of Commons Committee last Thursday, and was passed on by them to the Committee on Unopposed Bills. All parties may now be congratulated on the happy termination of a most delicate piece of work.

The agitation in Aberdeen over the alleged increase of charges for gas in the face of reduced rates came to a head on Monday, when a deputation representing the dissatisfied consumers, attended the meeting of the Town Council, and laid their grievances before that body. They acted with great discretion; avoiding the wild and random statements which have been rife of late, and eschewing the desire to lay any blame whatever on the Gas Committee. They asked for an inquiry by experts into the matter complained of, with a view to re-establishing public confidence in the management of gas-works. Several instances were given by speakers of increases of gas bills. Mr. Collie, the Convener of the Gas Committee, put several questions to the deputation, with reference to the number of consumers who had complained, out of about 26,000 in the city; but his questions were ruled by the Lord Provost as impossible to answer. Mr. Collie pointed out that of 16 gentlemen who were appointed a Committee to select the deputation, nine had had their bills reduced. Mr. Cook requested the deputation to furnish them with data upon which to proceed in making their inquiry, because, he said, the position of the deputation was not borne out by the books in the gas office. The Lord Provost suggested several reasons for the increased consumption, among which were enlarged mains, badly regulated meters, and inferior burners. The subject was sent to the Gas Committee, who met yesterday to consider it. A statement was submitted, showing that the income derived from the consumption of gas during last year exceeded by £600 the amount received the previous year; being about 6d. per head increase on 24,500 consumers. It was also stated that during the year 470 new meters and 70 street lamps had been added to the number already in use. The question of employing an expert was considered; and, after discussion, it was resolved to engage Dr. W. Wallace, of Glasgow. Dr. Wallace will have submitted to him a statement of the quantities and the qualities of the coal purchased during the last two years, together with a table showing the quantity of gas produced from the coal. Mr. Crau, the City Chamberlain, and Mr. A. Smith, the Gas Manager, were instructed to examine the books, and to prepare a statement setting forth the amount of the gas accounts for the last and the preceding two half years. The table will be prepared as applicable to the householders in three streets in different parts of the city. It is to be hoped that these measures will succeed in allaying the present agitation.

An abstract of the accounts of the Arbroath Gas Corporation for the year ending May 31 has been prepared, and will be submitted to an early meeting of the Board. It appears from it that the revenue from gas during the year was £8341 15s. 2d.; from gas-meters, £231 5s. 10d.; tar, £362 2s. 9d.; cinders, £49 9s. 3d.—making together £9034. Except on meters there was an increase on all these items. On the year's working there is a balance or surplus of £180 2s. 2d., as against a surplus of £41 18s. 6d. last year. The estimated surplus was £127. The price of gas during the year was at the rate of 4s. 3d. per 1000 feet; and as there was no rebate, this was practically an increase of 1½d. per 1000 cubic feet as compared with the previous year.

The Anstruther Gas Company have declared a dividend at the rate of 8 per cent. (which is ½ per cent. higher than the dividend of last year), and have been able to reduce the price of gas from 4s. 7d. to 4s. 2d. per 1000 feet. A year ago the Company reduced the price from 5s. to 4s. 2d.

At the annual meeting of the Alyth Gas Company on Monday, the Directors reported that the concern had been more prosperous than during the preceding year. A dividend at the rate of 7 per cent. was declared; and the price of gas was reduced from 6s. 3d. to 5s. 10d. per 1000 cubic feet.

The Brechin Gas Company have this year declared the usual dividend of £1 15s. per £10 share—equal to 17½ per cent. The Crieff Gas Company has paid a dividend at the rate of 5 per cent., and a bonus of 2½ per cent. The Wemyss Gas Company has declared a dividend at the rate of 6 per cent.; and the Pittenweem Gas Company has paid a dividend at the rate of 8 per cent.

The Dundee Water Commissioners, at their meeting on Thursday, adopted the annual accounts (which I briefly noticed in my "Notes" in the *Journal* for the 19th ult.), and resolved to reduce the domestic water-rate from 1s. 3d. to 1s. 2d. in the pound. The public rate was fixed at 1d. in the pound.

At a special meeting of the Edinburgh and District Water Trust on Monday, Mr. W. Boyd, W.S., was elected Clerk to the Trust, in room of the Hon. J. W. Moncrieff, who resigned a short time since. Mr. Boyd is the son of the City Treasurer, who is also a Trustee.

There was great rejoicing at Falkirk on Monday afternoon, when it was known that the Falkirk and Larbert Water Bill had passed the House of Commons Committee. The chief opposition to the measure was from the Carron Iron Company. The Committee, without calling upon Counsel for the promoters to reply to the arguments on behalf of the Carron Company, rejected their claim. The maximum rate for trade purposes was fixed at 4½d. per 1000 gallons. Owing to the heavy costs of promoting the Bill, the water-rate is likely to be pretty high.

(FROM OUR GLASGOW CORRESPONDENT.)

GLASGOW, Saturday.

At the ordinary monthly meeting of the Glasgow Corporation Gas Commissioners on Thursday, the question of using mineral oil as the source of gas was again introduced by Mr. McKellar, who suggested that, in connection with the extension of the Tradeston Gas-Works, provision might be made for testing oil gas, and trying what could be done with it. It was to be seen burning, he said, in the Exhibition; and the contrast between it and the gas manufactured from coal was so striking that everyone must be satisfied that there was a difference which was very much in favour of the oil gas. The Lord Provost remarked that when the matter was last before the Council, Mr. Ure, the Convener of the Gas Committee, stated that he was quite willing to receive any further information in regard to the question. Mr. Ure observed that since the time alluded to by his Lordship, he had had a visit from the gentleman who had been promoting the oil question; but, so far as he could learn, he did not appear to have arrived at a practical point on the subject. Hitherto all their experiments were with refined oil, which they found too dear, but he had been informed

that petroleum, or unrefined oil, might be used. The gentleman he had referred to was asked, about six weeks ago, to bring the question before Mr. Foulis; but, he had not done so. They were quite willing to test this unrefined oil, as their minds were perfectly open on the question. The Gas Committee was to a very large extent guided, and properly so, by the advice of their Engineer, Mr. Foulis, who was willing to make any experiments.

The annual meeting of the Ayr Gas Company was held on Wednesday. In the report submitted by the Directors, it was stated that during the past year there had been a slight rise in the price of coal, and that the average illuminating power of the gas supplied to the consumers had been 27.1 candles. A dividend at the rate of 5 per cent. was declared.

The annual meeting of the Saltcoats Gas Company was held on Wednesday. The revenue amounted during the past year to £1553; and the expenditure to £1152. It was agreed to reduce the price of gas from 4s. 2d. to 3s. 11½d. per 1000 cubic feet.

The Kilwinning Gaslight Company held their annual meeting on Tuesday. The accounts submitted showed that profits had been made during the past year to warrant a dividend of 8s. per share. In submitting the Directors' report, the Chairman made an interesting statement. The occasion, he said, was the last meeting of the shareholders of the Company, which was formed in the year 1836—52 years ago. All honour was due to those men who had the courage to undertake the work of supplying the town with the new light. Some persons invested freely, though with some doubts as to the scheme ever being likely to pay. The gas was distributed in the autumn of 1837, and was sold at 10s. per 1000 cubic feet. Of the original shareholders, there were only two now holding stock. By the year 1862, the number of shareholders had diminished from 81 to 58; and the dividend paid about that time was 10s. per share of £5, although transfers occasionally took place at £6 10s. per share. The price was reduced to 6s. 3d. per 1000 cubic feet in 1875, and the consumption of gas increased. In 1882 the price was reduced to 3s. 4d. per 1000 cubic feet; and the demand increased so much that in 1885 it was necessary to lay larger pipes in part of the town, and erect another holder. Owing to these and other circumstances, it was found to be necessary to raise the price of gas to 4s. 2d. per 1000 cubic feet, but the consumption continued to increase. He hoped that the new shares would be mostly taken up by the consumers, and thus keep them in the hands of those who were interested in supplying themselves with cheap gas. On the motion of Mr. Macrorie it was agreed to record a vote of thanks to Mr. Hugh King who had acted as Secretary of the Company since its foundation in 1836 until his recent retirement from active life, and for his energy and devotion to the Company's interests. A vote of thanks was also passed to Mr. Fulton for the able and intelligent manner in which he had fulfilled the duties of Chairman during the last eight years.

It is likely that the price of gas in Kilmarnock for the year 1888-9 will be reduced from 3s. 11½d. to 3s. 6½d. per 1000 cubic feet.

On Thursday, the annual meeting of the Blantyre Gas Company was held, when a dividend of 7½ per cent. was declared, and the price of gas was reduced from 4s. to 3s. 9d. per 1000 cubic feet. The Partick, Hillhead, and Maryhill Gas Company's shares were disposed of last Tuesday at 78s., 78s. 6d., and 80s. per share. It may here be mentioned that, during the year ending June 30, this Company's make of gas was increased to the extent of about 27,000,000 cubic feet.

The Glasgow pig iron market has been quiet but steady during the week; and Scotch warrants have fluctuated between 88s. 1½d. per ton cash, paid on Monday, and 87s. 9½d. yesterday. There is still a great absence of animation in the various centres of the iron trade. The stock of Scotch pig iron in the public warrant stores has now considerably exceeded a million tons.

Business is still good in the coal trade, more particularly as regards shipping sorts. There are somewhat active inquiries with firm quotations for main coal at 5s. 6d. per ton f.o.b. at Glasgow Harbour. Steam coal is in active demand.

The market for sulphate of ammonia was reported quiet yesterday at £11 5s. to £11 7s. 6d. per ton.

PROPOSED ELECTRIC LIGHTING OF SOUTHAMPTON.—"There is considerable prospect," says the *Hampshire Independent*, "that in the very near future the electric light will be permanently introduced into Southampton, and adopted by many of the large tradesmen. Negotiations are in progress for fitting up installations; and the project has been taken up with considerable favour in certain quarters. We do not, however, anticipate that shareholders in the Gas Company need trouble much over the possibility of the value of their property being depreciated. The battle between electricity and gas is one of long standing, and the gas companies hitherto have been well able to hold their own, as electric light shareholders have found out to their cost. Whatever demand there may be in Southampton for what some persons term the 'new light,' gas will be required as much as or more than ever; but as competition will be induced, the public will be sure to derive some sort of benefit."

GAS v. OIL FOR PUBLIC LIGHTING AT BROMLEY.—At the meeting of the Bromley Local Board last Tuesday, the Chairman said it would be remembered that when they negotiated with the Bromley Gas Company, they acceded to the proposal to continue the lighting, but at the same time agreed to inquire into the system of oil lighting. It seemed to him that he had only obtained a fictitious advantage from the Company, for while they were paying a lower price, they were receiving less benefit, as the Company extinguished the lamps at an earlier hour than before. He proposed that they should select a part of their district, at present not lighted, and put up as many oil-lamps as could be efficiently attended to by one man. They could then form a judgment whether oil lighting was suitable or not. The motion was carried unanimously. The Clerk stated that the Chairman of the Company had assured him that neither he nor the Directors had ordered the lights to be extinguished before daybreak.

A DRAINAGE SCHEME FOR CORK.—The Corporation of Cork have just had under consideration an important proposal for the efficient main drainage of the city. An elaborate report has been laid before the members of the Town Council by their Engineer (Mr. M. J. M'Mullen), who proposes to entirely change the drainage of the city at a cost of £94,708. He intends to remedy the defects of the water-carriage system of sewerage at present existing by making through the city 17 sewers, the dimensions varying from 12 inches to 2 ft. 6 in. in diameter; two reservoirs 300 feet in length and 60 feet in breadth; and pumping works adjacent to the reservoirs, consisting of two engines of 60-horse power each, so as to pump the sewage through the mains to a sewage farm of 300 acres. It is anticipated that the annual expense of the new scheme would be about £800; while the average cost of cleansing and maintaining the existing sewers is something like £2700. This saving of nearly £2000 per annum would represent a capitalized sum of about £40,000. The profits derivable from the sewage farm would be £600 per annum, or a capitalized sum of £12,000. Therefore, in order to gain a proper idea of the actual cost of the scheme, these sums of £40,000 and £12,000 should be deducted from the estimate.

CURRENT SALES OF GAS PRODUCTS.

LIVERPOOL, July 7,

Sulphate of Ammonia.—The continued absence of Continental orders, the reduction in Beckton quotations, and the operations of speculators, are beginning to tell upon the market; and although there is not a single circumstance apparent to warrant a lasting depression, it must be expected that values will suffer whilst these conditions supervene. The question of the hour seems to be, "Can consumers postpone their purchases much longer?" and it appears very doubtful whether they can. German buyers scan our markets eagerly, and they will have to disclose their position before the end of the month; while France is likely to be a much larger consumer than last year, judging from the requirements of the various "Syndicates," through whom the French farmers are supplied. One of the largest invites tenders for 185 tons of sulphate, but only 30 tons of nitrate; and it has evidently once more been found that for manuring late in the year, sulphate far surpasses nitrate in results. There is only a moderate quantity offering; and the probable consequences of any large orders can therefore easily be conceived. The market closes steadily at £11 10s. to £11 7s. 6d., f.o.b. Hull; £11 8s. 9d. f.o.b. Leith and Liverpool.

LONDON, July 7.

Tar Products.—Pitch continues buoyant. Whether this arises from the impossibility of shipping it during the warm weather, and the shortness of stocks at the fuel works abroad, or else to an increased demand for the article, it will be impossible to decide before the shipping season again commences. Distillers are remarkably short of all kinds of stocks, and are almost indifferent to the market values of any of the articles which, with the exception of pitch and anthracene, continue prostrate. It is stated that some of the buyers of high-priced tar are beginning to rue their bargain; as well they may, if present prices of products continue. Prices: Tar, 15s. to 20s. Benzol, 90 per cent., 2s. 5d. per gallon; 50 per cent., 2s. per gallon. Toluol, 1s. 4d. per gallon. Solvent naphtha, 1s. 1½d. per gallon. Crude naphtha, 30 per cent., 11d. per gallon. Light oil, 3½d. per gallon. Creosote, 1½d. per gallon. Pitch, 13s. to 16s. per ton. Carbolic acid (crude), 3s. 5d. per gallon. Cresylic acid, 10d. per gallon. Tar salts, 15s. per ton. Anthracene, 30 per cent., "A" quality, 1s. 4d. per unit; "B" quality, 1s.

Ammonia Products.—A good deal is being made of the reduced quantities of sulphate shipped to France this season, which it is stated only amount to one-half of last year's shipments to that country. If the report which comes from a good authority is correct, that nitrate of soda (which has been used in lieu of sulphate of ammonia) is giving unsatisfactory results so far, next year should bring a large demand for sulphate for France. Makers have no anxiety at the moment, as stocks are low, and new outlets are continually opening up. Prices: Sulphate of ammonia, £11 12s. 6d. to £11 15s. per ton, less discount. Gas liquor (5° Twaddell), 8s. per ton, with a rise or fall of 1s. 6d. per degree. Liquor ammonia, 2d. per lb. Carbonate of ammonia, 3½d. per lb. Muriate of ammonia, brown, £18 per ton; white, £28. Sal ammoniac, £30 per ton.

[From the *Chemical Trade Journal*, July 7.]

Sulphate of Ammonia.—The market is very dull; there being no inquiries from the Continent, so that it would be folly to name a price as representing the market value. No one would sell under the present circumstances unless forced to do so, as every parcel bought by the speculators at the present moment means so much weakness added to a future market. The present price is £11 10s. to £11 12s. 6d. at all ports. Fortunately there is not much offering, and stocks are small all over the country.

Tar Products.—The market for all tar products still remains quiet. Benzol remains much the same as in our last report, in spite of those who endeavour to depress it in order to cover sales on aniline already sold, and those who wish us to call it 2s. 7d. for 90's and 2s. 3d. for 50/90's. We think, however, it is a little firmer, though why it should be so we cannot tell, as Continental consumers are not buying. Solvent naphtha is in good demand at 1s. 0½d. to 1s. 1½d.; and a new quality is being offered, made from coke-oven oil, at 10d. Anthracene still remains at 1s. 1d. for "B" quality and 1s. 4½d. for "A"; while pitch is said to be firmer. We cannot see any very bright future for the pitch market, as heavy stocks are in the users' hands, and the patent-fuel market is not over brisk. The Salford tar has just been let to Mr. Hamor Lockwood, of Bradford and Miles Platting, and amounts to over 6000 tons annually.

REDUCTIONS IN PRICE.—The *Bury Corporation* have decided to reduce the price of gas to all consumers in the borough to 2s. per 1000 cubic feet net. At the meeting of the *Hereford Town Council*, last Tuesday, it was decided, on the recommendation of the Gas Committee, to reduce the price of gas 3d. per 1000 cubic feet; making the present charge 3s. 6d., with a discount of 3d. per 1000 feet.

GAS EXHIBITION AT HORNCastle.—An exhibition of gas cooking and heating apparatus was held at Horncastle in the last week in June; closing on the 29th. The cookery lectures by Miss Young were very well attended. The Chairman of the Local Board, in moving a vote of thanks to the lady, said the exhibition had been a decided success. The Board had received several orders for stoves, &c.; and he hoped the consumption of gas would be so much increased as to enable them to reduce the price of gas next year. The price was now only 3s. 2d. per 1000 cubic feet; and he hoped it might be less.

THE ROTHERHAM CORPORATION GAS UNDERTAKING.—At the meeting of the Rotherham Town Council last Wednesday, the recommendations of the Gas Committee to accept tenders for the coal supply for the ensuing year led to a long and acrimonious discussion, which ended in the adoption of a motion that the 1000 tons recommended to be purchased from Earl Fitzwilliam should be obtained from Messrs. John Brown and Co., and that the 1000 tons recommended to be purchased from the Greasbro' Coal Company, and the 1000 tons from Messrs. Newton, Chambers, and Co.; should not be purchased until after the same Committee had tested the gas-producing powers thereof. In the discussion, Mr. A. P. Hirst accused Alderman Gummer of insinuating that the members of the council had a little commission out of the contracts. Alderman Gummer said there was no doubt about it. Later on in the discussion, Alderman Newsum protested against the power which had been exercised by the Chairman and Vice-Chairman of the Gas Committee in testing the coal from Earl Fitzwilliam's colliery, and purchasing coal for this purpose without first obtaining the consent of the Committee. With reference to a proposal to call in the services of Mr. George Livesey to give the Gas Committee his opinion as to having increased purifying power at the gas-works, Mr. Cox opposed, and moved that the recommendation be rejected. He said he regarded it as the thin end of the wedge for engaging the services of a Consulting Engineer permanently. Mr. Cox's motion was seconded, but only three voted for it; and it was negatived by a large majority.

THE WATER SUPPLY OF BILSTON.—Last Thursday, a Committee of the House of Commons were engaged in considering an application by the Wolverhampton Corporation for a Provisional Order to alter the Wolverhampton Improvement Act, 1869, by allowing the Corporation to create a reserve fund of £10,000 in regard to the water undertaking, and to carry any balance of such revenue remaining in any year, and exceeding £500, to the improvement fund, or to use such balance in reducing the price of water to the consumers. The Bilston Commissioners, who are supplied with water by the Corporation at the rate of 5d. per 1000 gallons, petitioned against the Order, on the ground that they, as consumers of water supplied by the Corporation, ought not to be placed in the position of consumers in the case of a company trading for profit, but that in any event surplus revenue should be applied for the benefit of all the consumers alike, including Bilston. It was argued for the Corporation that Bilston could not complain of the Order, because they were bound by an agreement to a price fixed by an Arbitrator for 21 years. The Counsel for the Commissioners (Mr. Littler, Q.C.) attempted to raise the whole question of the water supply of Bilston; but this was objected to by the Corporation's representative (Mr. Balfour Browne, Q.C.). The Committee decided that they could not disturb the existing agreement; whereupon the Commissioners withdrew, and the Committee agreed to confirm the Order.

THE ADDITIONAL WATER SUPPLY FOR SKIPTON.—At a recent meeting of the Skipton Local Board, a report was read from Mr. Hill, C.E., who had been engaged by the Board to investigate the various sources of water supply in the neighbourhood. It deals with three alternative schemes—viz., Cawder, Potter's Gill, and High Skibeden. The one which would bring the water from Cawder into the existing reservoir by a pipe-line is estimated to cost about £5700; and the Potter's Gill scheme, which would also bring the water from this source to the present reservoir in a similar manner, is estimated to cost about £5000; whilst the additional supply of water from either of these schemes has been calculated, at the recent rate of increase, to serve the needs of Skipton until it has a population of about 15,000, some ten years hence. It is pointed out, however, that not one of these schemes would give an increased pressure to the existing water service, of the town which is so much needed at the highest points to which the pipes are laid. The Skibeden scheme is the one most highly recommended, because it is said to be capable of meeting all the needs of the town for the next 25 years. The scheme includes the construction of a reservoir at Higher Skibeden, which would cost about £12,000. This scheme would not only furnish a good supply of water, but there would be (in the opinion of the most competent authorities) sufficient pressure to meet all the requirements of the town for many years.

SALES OF SHARES.—Some miscellaneous shares in various Companies were sold by auction, by Mr. Alfred Richards, at the Mart, Tokenhouse Yard, last Tuesday. In all cases, the purchasers took the dividends accruing as from Jan. 1 last. The first five lots sold comprised in all 44 original £10 fully-paid shares in the *Brentwood Gas Company*, earning dividends of 10 per cent.; the price realized being £20 10s. per share. Four £25 additional shares (fully paid) in the *Chelmsford Gas Company*, producing dividends of 7 per cent., fetched £38 per share. An average price of £11 per share was paid for 30 £5 fully-paid "A" shares, paying a dividend of 10 per cent., in the *Romford Gas Company*. A parcel of 10 £10 fully-paid ordinary shares in the *Harrow District Gas Company* (the last dividend on which was at the rate of 7½ per cent.) sold for £15 15s. per share. 27 £10 original fully-paid shares in the *Carshalton Gas Company* (on which a dividend of 8 per cent. was last paid) produced £18 5s. per share; and 27 similar shares, on which £2 only have been paid, sold at £6 per share. Three lots consisting each of 10 £10 "A" fully-paid shares in the *Grays Gas Company*, bearing dividends of 7 per cent., sold at £16 10s. per share; and the same number of £10 "B" shares in the Company, earning dividends of £4 18s. per cent., sold at £12 a share. £9 per share was paid for 97 £5 fully-paid original shares (on which a dividend of 9 per cent. was last paid) in the *Harwich Gas Company*. Ten second issue £5 shares in the same Company (£3 per share paid), paying dividends at the rate of 6½ per cent., realized £5 17s. 6d. per share; and 10 similar shares, £5 15s.—Ten £5 "B" shares in the *Ossett Gas Company*, with the dividends shortly accruing, were sold by auction in that town last Thursday, at £10 5s. per share.—Ten original and fully-paid £10 shares in the *Pontefract Gas Company* were recently sold for £25 7s. 6d. per share; and 20 new £10 ordinary shares in the same Company for £11 2s. 6d. per share.

GWYNNE & BEALE'S PATENT GAS EXHAUSTERS AND ENGINES.

PLEASE ADDRESS IN FULL—

GWYNNE & CO.,ADDRESS FOR TELEGRAMS:
"GWYNNEGRAM LONDON."

HYDRAULIC AND GAS ENGINEERS, ESSEX STREET WORKS, VICTORIA EMBANKMENT, LONDON, W.C., ENGLAND.

TELEPHONE No. 2698.

Thirty-three Medals at all the Great International Exhibitions have been awarded to GWYNNE & Co. for Gas Exhausters, &c.

Only Medal at the Liverpool International Exhibition, 1886, for Centrifugal Pumping Engines.

They have never sought to make price the chief consideration, but to produce Machinery of the very highest quality.

The result is that in every instance their work is giving the fullest satisfaction.

They have completed Exhausters to the extent of 24,000,000 cubic feet passed per hour, which are giving unqualified satisfaction in work, and can be referred to.

ONLY 75 REVOLUTIONS PER MINUTE.

The above Engraving shows Two Engines driving Four GWYNNE & CO.'S PATENT NON-FLUCTUATING EXHAUSTERS, to pass 200,000 cubic feet per hour (without the slightest oscillation), at the EFFINGHAM STREET GAS-WORKS, SHEFFIELD.

Can be made, when desired, on their New Patent principle to pass Gas without the slightest oscillation or variation in pressure.

NO OTHER MAKER CAN DO THIS.

GAS VALVES, VACUUM GOVERNORS, REGULATORS, PUMPS, &c., &c.

Catalogues and Testimonials on application at the above address.

NOTICE TO SUBSCRIBERS

AS TO PAYMENT OF SUBSCRIPTIONS IN ADVANCE.

Subscribers who desire to avail themselves of the reduction in the Subscription to the JOURNAL by paying in advance for the second half of the year 1888, are reminded that this can only be done during the present month

The Subscription is at the rate of 21s. a year paid in advance, or 25s. if credit be taken.

THE JOURNAL OF GAS LIGHTING,
WATER SUPPLY, & SANITARY IMPROVEMENT.

TUESDAY, JULY 17, 1888.

MR. BRAY WINS.

On Friday last, Mr. Justice Kay, of the Chancery Division of the High Court of Justice, had before him Mr. George Bray's motion for an injunction to restrain the Council of The Gas Institute from giving effect to the vote for his expulsion which was passed at the last meeting of the Institute. When the case came on, it was announced on behalf of the defendants that, acting upon the advice of their Counsel, they would not dispute the plaintiff's contention, but would reinstate his name in the list of members upon payment of the regular

subscription; they bearing all costs of the action. A circular letter explanatory of the matter was sent to all the members of the Institute by the Secretary by the same day's post, so that they would be in possession of the facts from Saturday morning. The point of law upon which the event turned is very simple. The rule under which the proceedings for Mr. Bray's expulsion were taken is imperfectly drafted. It enacts that a member who shall have been guilty, in the opinion of the Council, of such conduct as shall have rendered him unfit to continue to belong to the Institute, may, after certain formalities, be expelled therefrom by a vote of "two-thirds of the members present." It is well known that the vote expelling Mr. Bray was carried at the meeting by 126 to 62; making a total poll of 188. It was obvious that this number did not represent all the members present. The President and the Secretary did not vote, neither did Mr. Bray; and several other members made no secret of their abstention from voting. It is manifest that if the words of the rule are to be construed with strict literalness, a margin of three non-voting members would have prevented this vote of 126 from being returnable by the President as the vote of two-thirds of the members "present." Mr. Bray quickly detected this flaw in the proceedings, and gave formal notice next day that, in his opinion, the vote was invalid; following up his protest by the legal action now under notice. The point having been submitted for Counsel's opinion, Messrs. Walter C. Renshaw, Q.C., and S. B. L. Druce declared that, in view of the decision of the Master of the Rolls in the celebrated case of *Labouchere v. the Earl of Wharncliffe* (the attempted expulsion of Mr. Labouchere from the Beefsteak Club), the words "two-thirds of the members present," in the 25th rule, mean two-thirds of the members present and entitled to vote, whether actually voting or not; and that, on the facts as stated, there was not a requisite majority in favour of expelling Mr. Bray. Consequently the Council had no case; and Mr. Bray triumphs.

It is, of course, easy to be wise after the event, and to see where the case for the Institute has broken down. It has been the practice recently, in drafting rules relating to the voting of members of clubs, &c., to insert, after such words as those in the 25th rule of The Gas Institute which confer the power of expulsion upon "two-thirds of the members present," the qualifying words "and voting"—which would have put Mr. Bray out of Court. This practice has been adopted with the object of getting over the difficulty created by the ruling of the late Master of the Rolls in the once notorious *Labouchere* case already cited. But The Gas Institute rules were not settled by Counsel, more's the pity. There is another consideration which affects the issue. The 35th rule says that no member whose subscription is in arrear shall be entitled to vote; and as there is a custom of paying subscriptions at any time during the meeting, it is practically impossible to tell at any given moment who is or is not duly qualified to vote. When the ballot in Mr. Bray's case was taken, it therefore now appears that every member presenting himself before the tellers should have been asked to prove that he was duly qualified to vote, and also to declare whether he wished to vote. He should then have recorded his vote; and when all the members had passed the ballot-box, their number should have been compared with the numbers of the balls in the divisions of the box. If this course had been followed, and only 188 members had passed into the hall, and constituted the meeting, the vote 126 to 62 would have been the legal two-thirds majority; but because this was not done, the whole proceedings for Mr. Bray's expulsion are invalid, and his name is to be restored to the roll of membership. It is the old story. Rules of societies are like Acts of Parliament and patents—very symmetrical and imposing until they are tested under the strain of a legal action, when they are apt to give way like wet paper. When one remembers what a fuss was made about the introduction of this supposed power of expulsion into the Code of Rules of the Institute, it is not without a smile that one can remark how little good it has been to the organization. The very first time it has been put in operation, it has landed the Institute in a very awkward predicament, entailing much irritating trouble and wasteful expense. Verily, in the matter of printed rules and regulations of all sorts, it is impossible to pronounce respecting their efficiency until they are tried. This notorious 25th rule of The Gas Institute has been like many other pieces of ordinance constructed at great trouble and expense—more dangerous in action to friends than to foes.

We congratulate Mr. Bray upon his victory, such as it is. It might be said that a man of any pretensions to sensibility would not avail himself of a legal quibble to escape the

consequences of an unmistakeable expression of public opinion; but, so far as we understand him, Mr. Bray indulges in no such pretensions. He is, indeed, quite justified in making the most of his legal triumph. The Council that recommended his expulsion were content with the narrow margin over the necessary two-thirds vote which they obtained at the meeting. They did not retire in dudgeon because the vote was not one of three-fourths, or nine-tenths, or any other fancy majority of the members present, with which they might naturally have been better pleased. Now it is Mr. Bray's turn; and he cannot be blamed for taking the fullest advantage of the relief which the law affords him. He has reaped the reward of single-minded devotion to his object, facilitated by a breach, not of his making, in the defences of his opponents. The merits of the case, of course, remain as they were. A man who escapes the gallows by virtue of that "flaw in the indictment" so dear to the typical Old Bailey practitioner, walks out of the dock a free man; but it needs something more to regain the esteem of his fellows. Mr. Bray has escaped the consequences of his misconduct in a way that does credit to his cunning; but nobody ever denied him the possession of this quality. Will anybody shake hands with him now who would not have done so last week? Certainly not. He remains what he was in the eyes alike of his admirers and those who despise him. It is unnecessary to discuss this part of the subject further. It is impossible, however, to resist the temptation to point out the remarkable contrast between the celerity with which Mr. Bray has sought his legal remedy in the present instance, and the repugnance which he has shown to taking a similar course for the enforcement of his monstrous claims against the Institute and sundry of its leading members. In 1886 he presented an account against the Institute for the considerable sum of £1194; and, though challenged to do so, he has never attempted to recover this amount by legal process. This debt probably yet stands against the Institute in the books of Mr. Bray's firm; but he has forgotten to demand payment. Does he treat all his debtors in this way, and forgive them if they do not pay on demand? If so, it is a curious way of doing business.

The natural question that will be asked upon the reception of the intelligence of last Friday's doings is, What is to happen next? We understand, from the circular to members already referred to, that the Council will find it necessary to "consider their position"—whatever this somewhat oracular pronouncement may mean. It probably signifies in the first place that a special meeting of the Council will be held forthwith to decide upon what shall be done. They owe this to the members, who will also wait with natural interest to learn the decision of their representatives in authority. It cannot be denied that the question is of the gravest importance in connection with the future of the Institute. A great muddle was made in the drafting and application of the rules, which competent legal advice, if taken in time, should have been able to prevent. It is idle to cry over spilt milk, however; and the mess having been made, the first duty is to wipe it up as neatly as possible. We do not propose to speculate upon what the Council may or may not do when they meet; but it may be at least permitted to us to predict that they will have plenty of matter to cogitate upon, over and beyond the immediate topic of Mr. Bray's enforced reinstatement. It would not be surprising if the Council should find themselves in face of a state of affairs to call for an extraordinary meeting of the Institute some time before the close of the current year.

A CONDEMNATION OF THE AVERAGE METER SYSTEM.

IN another part of the present issue of the JOURNAL will be found an interesting and important paper on the "Average Meter System," read by Mr. George R. Strachan, the Surveyor to the Chelsea Vestry, at the annual meeting of the Association of Municipal and Sanitary Engineers and Surveyors last week. It is not necessary to summarize the matter of Mr. Strachan's paper here; suffice it to say that it is a remarkable indictment of that system, to which such extravagant virtue in economizing gas has been ascribed by some municipal officers since it was first put into operation some twenty years ago. Mr. Strachan details a series of experiments by which he was led to perceive the fallacy of the name "regulator" as commonly applied to cheap gas-burners. It also appears that he detected a considerable amount of carelessness in the manufacture of real street-lamp regulators. But it is possible to accuse him of showing a little hypercriticism in his remarks upon this class of appliances; for, on the whole, the regulators tested seem

to have come out of the ordeal very well, considering that they were ordinary gas-fittings, and not philosophical apparatus. Indeed, Mr. Strachan is forced to admit after all that "regulator gas-burners can be made"—that is to say, are made, for he had some of them in his own possession—"which will not vary in their consumption of gas, at pressures varying from 1 inch to 4 inches, more than 1·15 per cent. fast and 2·3 per cent. slow of their average consumption." The conclusion drawn from this observation is that "regulator gas-burners can be made as correct as gas-meters." Hence the natural inference follows that the use of street-lamp meters is unnecessary. This opinion is fortified by a proof, drawn from experience, that the average meter system costs 9·9d. per annum, and the utmost that it can be credited with saving is 1·5d. per lamp per annum. This is a striking exemplification of municipal economy. Naturally, Mr. Strachan's revelations were criticized by some of his hearers—municipal officers who had advised their employers to adopt the average meter system. But they are clearly credible in the main; and it would scarcely be too much to say that the paper has dealt a severe blow to the superstition that meters are always a necessary or desirable appendage to public street lamps.

THE MONTHLY COLLECTION OF GAS ACCOUNTS.

IN another column we publish an intelligently-written communication from "A Manager Abroad" upon the subject of the monthly collection of gas accounts. It is notoriously difficult for an exile to keep himself acquainted with the current of contemporary thought in his native land; and when our friend across the seas expresses the opinion that the question of weekly, monthly, or quarterly collection of gas-rental is "at present agitating the minds" of his home-keeping brethren, this observation is forcibly recalled to memory. The fact of the matter is that, though the subject has undoubtedly been talked of in England of late, there is not half enough interest, to say nothing of agitation of mind, about it. The debates upon the topic have been of a particularly mild and academical character; and one can tell upon the fingers of a hand the gas managers whose interest in it has been sufficient to impel them to make an experimental departure from established usage. Our contributor settles the question, from his own point of view, in favour of monthly collections. It is certain that the system of monthly payments is successful in most foreign countries; and there is no real reason why it should not be adopted generally in the United Kingdom, except the unreasonable, but doubtless powerful argument of use and custom. As our contributor points out, there need be no compulsion about such a change, as those consumers who preferred to pay quarterly could still do so; and there is something in what he says about the ability of a large class of consumers to pay monthly accounts to the collector on demand, instead of asking him to "call again," as they now very generally do. We should like to hear from other gas managers who have tried both systems, as to which they really prefer, taking everything into consideration.

MORE OF THE CIRCULAR-OF-INQUIRY NUISANCE.

IN continuation of the notice of the circular-of-inquiry nuisance which appeared in the JOURNAL a fortnight ago, we may state that during the past few days we have received copies of letters, of the same character as that then commented upon, which we believe emanated from a member of the Board of the same Gas Company to which the inquiring Secretary belonged, addressed to gas engineers, with the object of obtaining gratis information upon matters connected with gas making. It is gratifying to learn that in at least one instance the honourable Director encountered the rebuff he deserved. He did not take it kindly, however, but replied with a tirade against the "discourtesy" of the Engineer who had refused to reply to his unwarranted inquiries. One is disposed to ask how much farther this sort of thing may be expected to go on. If a Gas Company's Secretary is to be charged with the duty of obtaining answers to one set of questions relating to gas management, while individual members of the Board undertake the task of getting information upon other points, out of any engineers with whose names they may happen to be acquainted, it is time indeed for the victims of these attentions to "strike." Let secretaries address themselves to secretaries, and directors to their kind; but it is necessary to inform these gentlemen that it is no part of the duty of engineers who may happen to be employed by Boards that know how to administer the property committed to their charge, to supply professional and technical information to

anybody but their own employers. We counsel all engineers and managers so approached either to consign these "fishing" inquiries to the waste-paper basket, or to briefly refer the inquirers to their own professional advisers. If they have not any qualified advisers, let them make good the deficiency as speedily as possible; for it is very certain that not all the secretaries and directors of all the gas companies in the United Kingdom, though they gave their minds to sending out and receiving replies to inquiry circulars every day of the week, could manage their gas-works as well as capable engineers. We are very loth to advise engineers to take a course which may be twisted into looking like reserve or incivility. But the evil to be combated has become a grievous one; and as it aims at nothing less than the destruction of the profession of gas engineering, and the working of gas undertakings "on the cheap," it is necessary to take strong measures for checking it. With reference to the protest from our clerical correspondent which will be found elsewhere, it should surely be unnecessary to point out that we have no desire to depreciate the value of a "clerical head" to a gas undertaking, so long as he keeps to his proper work. Secretaries as well as engineers have their place and part in the gas industry, which we should be the last to desire to take away from them. What we do condemn, however, is that subordination of the executive to the clerical element which seems to be in progress in some places. We hold with the preservation of a fitting balance between the two branches of administration; but if circumstances entail the supremacy of the one over the other in any case, we cannot agree that the engineering branch should be the one to succumb, for the reason that gas engineering is a speciality, while the work of a secretary and accountant is not. Any educated accountant, with a knowledge of finance and some acquaintance with company law and practice, can discharge the duties of secretary of a gas company, as of a railway, mining, or steamship company. A mining engineer could not properly manage a gas-works, however; nor could a gas engineer take charge of an ocean steamship. And as gas engineers cannot exist unless they are properly supported, we object to seeing them belittled and ignored by self-sufficient committeemen and directors or ambitious secretaries.

A CONTINENTAL VIEW OF SACCHARINE.

THE coal-tar sugar, saccharine, is greatly exercising the customs authorities of those Continental countries in which common sugar is heavily taxed. The use of saccharine as an adulterant does not affect us much in the United Kingdom, because of the cheapness of refined sugar; but it is a very different thing in places where, what with customs and *octroi* and other impositions, sugar generally sells at from 6d. per pound upwards. Under these circumstances, the confectioners have, of course, found out the advantages of saccharine. A trade recipe shows that 10 grammes of saccharine mixed with 5 grammes of bicarbonate of soda and dissolved in a litre of warm distilled water will replace about 3 kilogrammes of sugar. No sooner had this statement seen the light in a German publication, than the sugar refiners were all up in arms against the intruder. What was the use of encouraging the sugar trade by the bounty system if this chemical preparation was to be allowed to undermine the business of the refiners? It began to look as though the ruin of Jamaica and Demerara would be avenged by Newcastle coal tar, when a chemist came to the rescue and showed how by a "simple" test the presence of the intruding sweet may always be detected. All one has to do is to treat the suspected article of diet with a few drops of sulphuric acid, and then to add water, if the substance requires dilution. Equal parts of petroleum and ethylic ethers are then to be added, and the whole shaken up. After the reagents are evaporated, the residue is to be dissolved in hot water. The solution is to be finally divided into two portions—one to be kept for testing for salicylic acid, and the other to be tasted for saccharine, which will be revealed by its energetic sweetness. That is all; but well may the writer in the *Revue Industrielle*, from whom we obtain these particulars, declare that if this sort of thing is to go on, it will be necessary to retain chemists to be responsible for the bills of fare at restaurants.

THE CHARGE OF LIBELLING MR. W. J. WARNER.—At the Durham Assizes yesterday, Richard Cunliffe, who was committed for trial at the South Shields Police Court on the 25th of April last (as reported in the JOURNAL for May 1), on a charge of having made certain libellous statements concerning Mr. W. J. Warner, Manager of the South Shields Gas Company, surrendered to his bail, and publicly withdrew the charges; apologizing for having made them.

Water and Sanitary Affairs.

THE investigations conducted during the last quarter of a century into the presence of micro-organisms in air and water are brought under review in an interesting article contributed to a recent number of *Nature* by Dr. Percy F. Frankland. The multiplication of microbes in natural waters, practically devoid of organic matter, is one of the puzzles of bacteriology. Water obtained from deep wells in the chalk is cited as an example of effective filtration through the action of the intervening strata; for while river water contains some thousands of microbes in a cubic centimetre, the chalk wells yield water containing as an equivalent only eighteen microbes, on an average, for the year. But this same water, if kept for several days, although thoroughly protected from atmospheric contamination, is found to contain an enormous number of micro-organisms. Dr. Percy Frankland says: "From what source such organisms obtain 'their necessary nourishment under these circumstances, 'has not yet been determined.' Some of the water organisms are even capable of this abundant multiplication in water which has been several times distilled, and which is, therefore, almost absolutely pure. The extent to which this process goes on, is shown by a sample of water from one of the deep chalk wells belonging to the Kent Company. On the day of collection, there were seven micro-organisms per cubic centimetre. The next day there were 21 of these; and in three days the number was nearly half a million. Minute as these creatures are, such teeming life, with seemingly nothing to support it, is little short of marvellous. The practical conclusion arrived at is that the examination of water for the number of micro-organisms present can have no value if this kind of multiplication has previously taken place. Accordingly, if the number of these organisms present in a water is to throw light on the 'natural purification' it has undergone, the sample for examination, Dr. Percy Frankland says, 'must be taken as near as possible to 'the point where it issues from the water-bearing stratum.' So also in the case of 'artificially purified' water, we are told that the sample should be taken 'as soon as 'possible after the water has left the purifying apparatus.' It was for this principle we contended some time ago, when comparisons were made between water as pumped from a Kent well, and as drawn from the main of a Thames Company. Vicinity to 'the purifying apparatus' would suggest, for example, that the sample of the Chelsea Company's water should be taken somewhere near the exit from the filter-beds, or where the supply quits the service reservoir, instead of being drawn from a stand-pipe on the cab-rank at the Horse Guards. As the monthly samples are taken at spots selected by the several Companies, it might be judicious for the Directors in each case to consider whether they are doing themselves justice. What may take place in the mains, is indicated by the experience of the Kent Company. In May last, while the micro-organisms in samples taken from the three deep wells at Deptford were less in number than in any part of the Thames and Lea supply, the case was reversed in respect to the sample taken from the Kent Company's main in Mill Lane, situated at a short distance from the wells. In this latter instance, the microbes were numerous enough to exceed the proportion in all the remaining Metropolitan supplies, except that of the East London Company. Judged by the microbes at Mill Lane, the Kent supply stood second on the list of excellence, although the samples from the wells placed it at the head. Dr. Percy Frankland's article in *Nature* confirms this record; seven microbes in the Kent water becoming 495,000 after being kept three days. The sooner the water gets through the mains, therefore, the better. On the great reduction in the microbes which results from the storage and filtration practised by the River Companies. Dr. Percy Frankland is perfectly explicit. The results are admitted to be 'striking;' and we are told 'there is no 'doubt that, with the introduction of fresh improvements and 'increased care, an even greater reduction will be effected.' Concerning the actual detection of harmful or pathogenic forms of bacterial life, Dr. Percy Frankland argues that the point is of very little importance, the removal of micro-organisms in general being a sufficient guarantee for the removal of those that are hurtful. It is also proved, by experiment (for which we think Messrs. Crookes, Odling, and Meymott Tidy may be cited), that ordinary drinking water does not afford a suitable medium for the development of pathogenic forms.

The Gas Institute.

PROCEEDINGS AT TWENTY-FIFTH ANNUAL MEETING.

CHARLES GANDON, Esq., M. Inst. C.E., PRESIDENT.
PAPERS AND DISCUSSIONS.

(Concluded from p. 64.)

ON THE LATEST IMPROVEMENTS OF THE GAS-BALANCE.

By FREDERICK LUX, of London.

At the meeting of the Institute in Glasgow last year, I had the pleasure of giving you a detailed description of my apparatus for the determination of the specific gravity of gases—the “gas-balance.” Having since then modified and perfected the apparatus in several respects, I once more venture to trespass upon your indulgence by laying before you a few new facts connected with this matter.

You will perhaps remember that the receiving vessel for the gas in my former apparatus—models A and B—consisted of a glass globe, holding 1-15th of a cubic foot. [See JOURNAL, Vol. L., pp. 177-78] I have now replaced the glass globe by a brass sphere to contain only 1-30th of a cubic foot, or of one-half the capacity of the former; thereby securing two advantages—viz., a decreased liability to fracture; and the possibility of exchanging the gases in one-half the time which this operation previously required. The bores, moreover, in these new models C and D (figs. 1 and 2), have been made wider; so that by this arrangement the outflow of the gas is both easier and quicker—the result being that, with these new models, only from three to five minutes are required to replace the total contents of the globe by fresh gas, which operation, in models A and B, took fully from ten to twelve minutes to accomplish.

In order to give facilities for testing at any time the temperature and pressure of the gas in question, I have added, in convenient places, thermometers and manometers; and as the apparatus is intended to be used in all parts of the manufacture of gas, I have enclosed it in an oak case, which is glazed over, and capable of being put under lock and key. It is thus perfectly safe from dust, from being tampered with, &c. The case is supplied with a spirit-level and regulating screws, so that the balance can at any time be examined as to its horizontal position. A thermometer and barometer fixed inside the case serve for the determination of the temperature and the pressure of the air. In model C (with gas supply and outflow), only the front side of the casing can be opened; but in model D (with gas supply and burner-pipe), the lid is also arranged for opening. As the case in apparatus D must be opened while the apparatus is at work, and in model C it may remain shut, the latter deserves the preference. The four models mentioned give the specific gravity exactly to within $\cdot 01$; and are, therefore, sufficiently accurate for ordinary everyday use.

For calculations requiring greater accuracy, I have constructed model E (fig. 3), which, in several respects, differs from the other apparatus. The balance rests, not on points, but on an edge, and is so arranged that, while the apparatus is not in use, the edge is lifted off the bearing, and in whatever position the balance may happen to be, it can be retained there. For the purpose of avoiding the large angular movements experienced in the case of the other apparatus, I have furnished the balance with a weight, which can be shifted to and fro on the beam; the division marked upon the beam giving the first two decimal places, while the pointer of the balance, moving in a graduated arc, which is fitted somewhere below, indicates the third decimal place. We may, with the aid of this balance, determine the specific gravity of any gas to within $\cdot 001$. In every other respect, the balance is fitted up exactly like the other apparatus.

Model F (fig. 4) is intended for determining the constituents

FIG. 1.

FIG. 2.

FIG. 3.

of gaseous mixtures—as, for instance, the quantities of carbonic acid and sulphuretted hydrogen present in illuminating gas. The beam carries on each side a brass globe, which serves as a receiving vessel. The gas to be examined flows first through one globe; then through an absorbing or purifying vessel, in which, to mention one example, the carbonic acid may be retained; and, further, through the second globe. The change in the specific gravity, made by the elimination of one constituent, is commensurate to its quantity. As with gases of an average specific gravity of $\cdot 5$, one per cent.

FIG. 4.

FIG. 5.

FIG. 6.

of sulphuretted hydrogen causes a difference in specific gravity of $\cdot 006$, and one of carbonic acid a difference of $\cdot 01$, and as, moreover, the balance is capable of accurately indicating a difference of $\cdot 001$, the sulphuretted hydrogen in ordinary illuminating gas can be determined to within 1-6th per cent., and carbonic acid to within 1-10th per cent.

In conclusion, I wish briefly to refer to model G (fig. 5), which is capable of automatically registering the specific gravity of gases during their passage. In this self-registering apparatus, we cannot, of course, expect a connection with any

writing arrangement; for the simple reason that a difference of $\cdot 01$ in the specific gravity of gases corresponds to a difference of only about 1-5th of a grain in weight. The marking, on the contrary, is done by photographic means; the higher or deeper position of the beam being registered by a ray of light (which passes through a bore of the beam) upon a strip of sensitive paper. This paper, by means of clockwork, is moved along in a dark casing, and is slowly drawn across a narrow slit. By means of an apparatus of this kind, I have succeeded in marking the specific gravity of gas in gas-works; and the registrations obtained (see next page) actually indicate the variations which result from the operation of filling the retorts. We may, therefore, anticipate that this apparatus will show its usefulness in controlling the working of furnaces, &c.

Of additional apparatus, specially constructed for use with the gas-balance, I may mention the gas-filter, which can be utilized for the retention of water and tar in crude gas, of particles of dust, &c., in generator and fire-gases. There is also an apparatus (fig. 6) for absorbing moisture, carbonic acid, sulphuretted hydrogen, &c.; and, lastly, an appliance for the cooling of hot gases.

Allow me to add that the gas-balance, in ordinary working, has proved a very useful apparatus; and Mr. W. A. Valon, of Ramsgate, among others, has given a very favourable account of its practical value.

Discussion.

The PRESIDENT said in these days of demand for improvements in gas manufacture, anything which would enable them to test and analyze gas in an easy manner must be welcomed by everybody. He was much struck last year by the simplicity of Mr. Lux's gas-balance; and no doubt the improvements now described would add to its utility. The paper did not admit of much discussion; for without a careful examination of the apparatus, it would be difficult to express an opinion upon it. He would merely ask the members to record a vote of thanks to Mr. Lux for his paper.

Mr. J. SOMERVILLE (London) said that this was a matter of rather more importance than was generally attached to it. Some 14 or 15 years ago, he had considerable experience in testing for carbonic acid in furnace gases, and had had a great deal of difficulty in doing so. He used Wright's balloons and glass globes, and Dr. Bunsen's and Schilling's apparatus for effusion tests. But he could never get a satisfactory and straightforward determination; so that, after considerable difficulty, he had an arrangement made very similar to Mr. Lux's, consisting of a glass globe at the end of a beam. Mr. Lux, however, had very much improved the instrument. He described his own arrangement in the *JOURNAL OF GAS LIGHTING* in 1875,* when he proposed that it should be connected (as Mr. Lux had now made it) with an automatic photometer. His experience was that when all the moisture and carbonic acid was taken out of the gas, the balance acted accurately as a photometer. He found, from a number of experiments extending over several months, and working with gas from 14 to 24 candles, that 14-candle gas had a specific gravity of about $\cdot 440$; 15-candle gas, $\cdot 450$; and so on, up to 19-candle gas, which had a specific gravity of $\cdot 490$. But when it came up to 20 candles, there was a difference in the constitution of the gases; and he found that from 20 to 24 candle gas, the numbers went at the ratio of $\cdot 15$ for every candle; so that, although 20-candle gas gave $\cdot 500$, 24 gave $\cdot 560$. He could depend more upon this than he could on the photometer, although he had too much friction in his balance; but he believed Mr. Lux had succeeded very well with a jet of light on sensitized paper. If he could depend on doing this, and they could set up a machine which would be independent of gas examiners or managers, it would be a very great advantage. It was always an anxious time for a gas manager each morning before he saw the examiner's report as to the previous night's test; and an apparatus of this kind would be hailed with great satisfaction.

* See Vol. XXVI., p. 793.

THE SPECIFIC GRAVITY OF LIGHTING GAS RECORDED BY PHOTOGRAPHY IN LUX'S SELF-REGISTERING GAS-BALANCE.
Duration of the Experiment, 24 hours; Gas taken off after passing the Station Meter.

Mr. NORTON H. HUMPHRYS (Salisbury) believed it was usually the custom to have a vessel containing chloride of calcium or sulphuric acid in the glass case for the purpose of absorbing moisture; but he did not see any arrangement here shown for that purpose. He was in the habit of using a glass globe, about 7 inches in diameter, which contained $\frac{1}{4}$ foot of gas, with a delicate pair of scales; and he found that, by taking care of the moisture, and, of course, with accurate thermometers, he obtained very good results. It was necessary to keep a perfectly dry atmosphere inside the glass case, in which the balance was contained.

Mr. W. A. VALON (Rainsgate) said he had not had one of the latest balances; but he had tried one of the others, and found it exceedingly useful. He thought, however, to make them accurate, a little square box was wanted, through which to pass the gas to extricate the moisture; and it then became a very good check on the quality of the gas. The foreman could tell immediately if anything was going wrong. Hitherto, by knowing nearly what the specific gravity of the gas should be, they could tell what was going on, and had been able sometimes to regulate the charges of new benches, so as to get the makes fairly regular. In furnace gases once the specific gravity of the constituents were known, it was easy to make a very rapid estimate, which would tell whether or not the furnace was doing its duty.

Mr. Lux, in reply, said, if he understood aright, Mr. Humphrys objected that there were no absorbing materials in the interior of the case to dry the air. He had made some experiments with a hydrometer in the interior, and determined the moisture of the air; and he found that it varied only very little—from about 40 to 60 per cent. Without the absorbing materials, he obtained a percentage of only about 35 to 45; so that, for ordinary purposes, it would not be at all necessary to adopt this precaution.

SANITARY INFLUENCE OF HEATING BY GAS.

By LEWIS W. LEEDS, of London.

In saying that I believe thousands of lives and many millions of money would be saved by the general adoption of gas for warming our houses, I do not want to be understood as asserting that the heat from a gas-stove is more wholesome than that from the ordinary open fire; quite the contrary, I wish it to be understood at the start that I consider the heat from the open fire the most wholesome artificial warmth known. It is the nearest imitation of that magnificent heating power that the ancient heathen so devoutly and sensibly worshiped—the sun. It is not the quality that we want improved; but it is the quantity. Every one is satisfied with gold to fill his pockets with. But sometimes we cannot get all the gold we want; and then we are willing to take silver, or even accept copper. So with the heat from the open fire, it is very good what there is of it. There are, however, many parts of houses where we cannot easily get from the open fire the necessary amount of pure radiant heat needed to maintain good health; and in such cases, we require the best possible substitute. Gas appears to me to offer an excellent means of securing this substitute; but it is of the utmost importance to know that we make the proper application of the gas to secure the best results.

Heating by gas is much more liable to abuse than heating by the ordinary open fire. The deadly products of combustion from the open fire are so disagreeable that one of the first steps towards civilization taken by any members of the human family was to get clear of the smoke from their dwellings. The products of combustion from gas are almost as deleterious to health as those from the ordinary fire; but, unfortunately, they are less conspicuous, and consequently we have, as yet, sadly neglected using the necessary precaution to have these unwholesome products of combustion scrupulously removed from occupied apartments. We cannot get the fire to burn readily without a good draught, which ensures the carrying away of the products of combustion. This guarantees us, in a certain measure, against the abuse of allowing these to remain in the room. But with gas it is different, as that will burn in a room without any flue or exit for the escape of the products of combustion; and hence its greater danger. But

with a little study and thoughtfulness, this can be easily remedied.

One of the most important points in connection with artificial heating is the fact that the air is not warmed by the rays of heat which pass through it. This we may say is the fundamental principle of all heating, either natural or artificial. Many suppose that, for the persons to feel warm in a room, it is necessary for the air in that room to be heated. This is a great mistake. The air ought not to be warm, but should be cold, because it is necessary for health and vigorous strength that we should inhale cold air. The colder the air we breathe, the more rapid the circulation of the blood. The whole action of the system is twice as great when inhaling air nearer zero, than when inhaling air nearer the temperature of the body.

Now the important question arises, How shall we keep the blood warm, while being surrounded with, and inhaling this cold and invigorating air? for we know, if the blood is allowed to cool only a very few degrees, it is certain death. The extra warmth may be maintained by additional clothing, which is often debilitating, or by exercise, which exhausts the animal strength. But now comes to our relief that beautiful and very wise provision of the radiation of heat. We can have our bodies warmed by the direct rays of heat from an open fire or any other hot substance, without having the air warmed. This is a grand arrangement. Now, we want to familiarize ourselves with this one great and important fact, because our health and comfort is affected more or less by clearly understanding and knowing how to readily apply this principle of keeping ourselves warm while being surrounded with, and inhaling cold, invigorating air.

One of the greatest difficulties connected with this subject is to prove, by actual demonstration to the sight, the passage of the rays of heat through the air, and to prove also that these rays of heat do not warm the air as they pass through it. Of course, we have the familiar illustration of the heat received by radiation from the sun. We know that in winter, when the air is so cold that it is freezing on the shady side of the street, a thermometer hung in the sun, and protected from the air, would rise to 150° or 200°. We are surrounded constantly with many illustrations of this important principle; and we should make ourselves intimate with the best means of applying it for maintaining health and comfort. Professor Tyndall has given much study to this subject, and has tried a great variety of experiments. He has purified the air; removing from it the obstructing substances mechanically suspended in it—such as moisture, dust, and in London a great amount of smoke, which had to be taken out before he could tell what the effect would be with pure air. He succeeded in getting the air to a condition in which it arrested such a small fraction of the rays of heat, that he came to the conclusion if it was absolutely pure, it would not obstruct a particle of the radiation; or, in other words, pure air formed an exception to all ordinary substances, in the fact that it would not obstruct or absorb radiant heat.

I fear we cannot do much towards illustrating this beautiful principle by any crude experiments we can perform here. We

FIG. 1.

have, however, a very rough affair, which may give some idea. We have simply taken one of our ordinary circular gas-stoves, and suspended it about 15 feet high; and by removing the bottom, we get the radiation directly toward the floor. We have placed below it an 8-inch tube, about 12 feet long. This tube is open at both ends; and there is a rapid circulation of air passing up it, as you may see by the smoke from this paper. But directly in opposition to this ascending current of cold air, there is a strong descending current of radiant heat. We will place a thermometer directly below the tube and see how rapidly it rises. We will also see if it will light this candle. There you see it is lighted in 50 seconds. We have placed a thermometer on top of the stove; and will look at them both again in 10 minutes, and see what effect the heat has had upon them. Here you see how these rays of heat descend through this long tube in direct opposition to

the strong ascending current of cold air. I cannot show you how little the air is warmed by the rays of heat; but very careful scientific experiments have demonstrated that the air is not warmed in any degree. The thermometer below the pipe has, you see, risen to 120° in 10 minutes; and the one on top has risen 5° . You thus see how totally independent are the movements of the air and the movements of heat—radiant heat, I mean.

Having thus got this great fundamental principle of radiation clearly in our minds, we can proceed to apply it to the various arrangements for artificial warming. I call it "artificial," because this principle is most beautifully applied in the natural heating by the sun, in which the rays of heat are not absorbed by passing through the many miles of air surrounding the earth, but are first obstructed by the solid substances at the earth's surface—at the very bottom of this ocean of air; and then the air is warmed by each individual particle coming in actual contact with these warmed substances. This heated air rises; and the colder air from above falls down to take its place. This is Nature's great method of warming and ventilating. How can we most nearly imitate it? We must notice distinctly that Nature's main principle is to warm the floors; and we may almost say this is the only warming she does. With the solid floors of the earth warmed, and colder air above, excellent ventilation is at once secured, because this creates a perfect agitation and circulation over the entire heated surface. Now what we have to do is to imitate this as nearly as possible. The great difficulty we are hampered with is that we have a roof just above our heads, and walls on all sides of us, which confine and obstruct the circulation of the air. This cannot be helped; and so we must put our ingenuity to work to overcome these difficulties the best we can.

If we could get an even temperature of 98° over the whole floor, which would be the normal temperature of our bodies, and would consequently feel neither warm or cold, and if we could have a constant supply of pure air in the room at a temperature of 52° , we should have a splendid arrangement—almost equal to the sunshine. There are various ways of warming floors; and our most thoughtful architects and engineers are giving much attention to devising practicable methods for accomplishing this very desirable object. The luxurious old Romans took great pains to warm the floors of their palaces. Steam and hot-water pipes are now frequently employed in large buildings for this purpose; but it is a slow and elaborate process to get the necessary warmth by these methods. If similarly good results can be obtained by using gas, with the great additional convenience of being able to get the heat instantly whenever required, and to be dispensed with when not needed, it will be a most valuable point gained.

It is with the view of securing these advantages that we have devoted much time and thought to devising and completing a system of warming by gas-stoves, which might secure these important conditions. I have here a specimen of these stoves, in which you will see that we use a row of ordinary gas-burners. Over these burners we place an arch of asbestos, from which are suspended fine filaments of asbestos. You will notice, as I light the gas, this asbestos floss is instantly made red-hot; it scarcely requires a quarter of a minute to become heated to a bright red. I have placed six candles on the front of the stove, which you will please notice carefully. The first one lights in 27 seconds; Nos. 2, 3, 4, 5, and 6 are all lighted in less than 55 seconds. This shows the instantaneous effect of the downward radiation of the heat. You will also observe what a pure white flame the gas gives; and from this and the perfect whiteness of the asbestos, you will see we secure excellent combustion. This is the first necessity—the securing of perfect combustion, so as to create the greatest amount of heat possible from the consumption of a given amount of gas. The location of the burners in a chamber closed at the top, making a reservoir of hot air, from which the burners are supplied, undoubtedly assists in perfecting the combustion. The absence of the ordinary disagreeable odour given off when burning gas in the open room, is due to this complete combustion.

The second point to be considered is, How to get the heat where we require it? The tendency of heat is to rise immediately to the ceiling. But it is of no use there. We must therefore endeavour to prevent it ascending; and direct it to the floor, which is the only place where it is required. Many eminent engineers have wasted much time and thought in trying to keep a stratum of warmed air on the floor, without heating the ceiling of the room excessively; and many millions of money have been thrown away upon these

vain efforts. It may be considered practically an impossibility to make a thin stratum of warmed air lie on a cold floor with cold air above. I have spent a large part of my life in endeavouring to make what may be called the American system agreeable—that is, the method of attempting to warm our houses by over-heating the fresh air supply. This plan, however, is radically wrong. It is unnatural, because in Nature we find the solid substances hotter than the air. But now that we have discovered the valuable property of radiant heat, and find that these rays do not warm the air in passing through them, we have the key to the whole subject. You will see, by these thermometers lying on the floor, that the heat from the underside of this red-hot arch has been radiated to the floor, so that the thermometer indicates 150° . I have another thermometer nearer the fire surrounded by a double tin tube (which shields it from the radiant heat) open at both ends, which allows a free circulation of the air; and this only indicates 76° . This gives the temperature of the air close to the fire, so that you see the air is not heated. We also have a thermometer hanging immediately above the stove, which indicates only 81° . In addition to the heat radiated to the floor, there is a second important process. The products of combustion are confined in this enclosed chamber over the burners long enough to impart to the sides the remaining heat not radiated to the floor. A secondary radiation takes place from the warmed sides of this chamber; thus utilizing most effectually all the available heat.

For further illustrating the effect of warming the floor by downward radiation, we have, in the accompanying tables [see next page], the results of experiments tried by The Gaslight and Coke Company. In those tests a circular stove (Fig. 2), 13 inches diameter and 54 inches high, was used. There were four ordinary burners, consuming, on an average, $13\frac{1}{2}$ cubic feet per hour. You will notice that the thermometers Nos. 1 and 1A were placed on the floor, about 18 inches from the burners. They were put back to back; No. 1 being turned towards the burners, and consequently receiving the full force of the radiation from the heated asbestos arch. No. 1A was screened from the radiation; but, as it was within 2 or 3 inches of the other, and there was a free flow of air round them, both thermometers must necessarily have been in air of precisely the same temperature. It is scarcely possible that there could have been a variation of $\frac{1}{4}^{\circ}$ in the temperature of the air surrounding the two thermometers. The difference indicated by the thermometers is about 115° ; and this therefore shows the amount of heat radiated on the floor at that point. By comparing No. 2 (which was on the floor, under the window, and from 3 to 4 feet from the stove) with No. 6 (which was near the ceiling), we see there was some 23° more heat radiated on to the floor at that point than there was near the ceiling. Again, by noticing the record of No. 7, which was hung directly over the stove, we see there was some 15° more heat on the floor under the window than there was immediately above the stove. The figures given in these tables are not the outcome of mere guess work; but are the results of experiments carefully and accurately made. They prove, in the most conclusive and comprehensive manner, how floors may be warmed by downward radiation, while at the same time there may be a free and rapid circulation of the air through the room, which will be but slightly warmed. These results are of the greatest practical value in artificial warming.

The second table gives the figures derived from experiments with a stove of similar external appearance (Fig. 3), and which I supposed would show results much nearer the first than it did. You will see that the thermometer No. 1, which was placed in a similar position directly in front of the stove, only rose 5° the first hour, instead of 125° —certainly a very remarkable difference. This stove had the corrugated copper back, and reflected the light very similarly to the one invented by me; but although they look alike, the results as you observe, are very different. But if you will look at No. 7, you will readily imagine what becomes of the heat— 148° in one hour according to the table with the door open, or 159° when the door was shut. This, of course, is the very common result of artificial heating. Hot heads and cold feet—a most unnatural and distressing condition of things. With this latter system of heating, it is absolutely necessary to close up all the ventilators at the ceiling, in order to prevent the heat from escaping there, and leaving the floors cold.

Therefore, by the method of floor warming by direct radiation, we have a principle quite similar to that

Remarks.—The thermometers indicated by "A" were placed at the back of the others. Average consumption per hour 11·6 cubic feet.

of heating by the sun, but with one very important difference. In heating by the sun there is no trouble with products of combustion; and how to get rid of these products from gas stoves is an important problem. All artificial sources of heat—either gas, lamps, chandeliers, or coal fires—should have, if possible, a separate flue for removing the products of combustion immediately from the room. This matter has been much neglected heretofore in all arrangements for lighting by gas. There is now a disposition amongst our more thoughtful architects and engineers to give this special subject much more attention. There should always be in the ceiling of a room a good exit for the vitiated air. With such an exit the products of combustion from the gas-stove would also escape. You will see by the smoke from the taper I have here that, notwithstanding the heat is much the greatest on the floor, the products of combustion, as they escape from the under side of the front canopy, are still warm enough to rise through the colder air of the room. We must remember that this ascending air does not carry with it the rays of heat; therefore there may be a rapid escape of the air from the ceiling of the room with a very small proportion of loss of heat. This explanation applies to rooms or places where no flue is available, such as shops, the front entrance, halls in dwellings, many offices, and a large number of places where there is no heat at present owing to the want of a flue. This principle of radiant floor-warming is a great boon to such places; because it is possible in nearly all such positions to obtain proper circulation of air by lowering a window or by an open stairway, or by providing some similar means of escape.

You must bear in mind that the most important part of the condition of heating the floors by direct radiation is that you can have a free circulation of air for ventilation without creating unpleasant draught on the feet. Of course, where there is a flue or an open fireplace available, it is the simplest thing possible to set the stove in front of the fireplace; leaving the whole chimney open for ventilation. The great advantage of this arrangement is that with the stove directly in front of the open chimney, you may have a large volume of air flowing by, and thoroughly ventilating the room, without wasting the heat from the fire. This is a very valuable feature; but it will require a little careful reflection to realize the full importance of it. A clear understanding of this, however, will explain how a large room may be comfortably warmed with gas during two hours for 1d., and at the same time be thoroughly ventilated.

Now, in considering the sanitary value of this system of heating, we must first notice the great deficiencies in the present methods. By consulting the mortality reports, we find that the death rate increases very rapidly, especially in the large cities, in cold, damp weather. The record of deaths is almost as true an indication of the changes in the atmosphere as the thermometer itself. During the siege of Paris, careful observations were made in the city to ascertain the effect of cold on the death rate. It was found that the want of fuel, as indicated by the increased death rate for every degree the thermometer fell, was greater than the want of food. In American cities, where the system of evenly warming the whole house is much more common than it is here, this great increase in the death rate in cold weather does not occur. As I have already said, I have a high appreciation of the quality of heat obtained from the open fire so generally used in this country; but the great drawback is that we do not thoroughly warm, dry, and ventilate our apartments with this dirty, troublesome, and expensive system of heating. The halls and passages are almost invariably cold and damp; and, on account of the difficulty of making a fire in the ordinary grate, the bed-rooms are very frequently left cold and unaired. Much discomfort and suffering, excessive sickness, and a high death rate are the natural consequences.

England has clung very persistently to her dirty, troublesome, open coal fires. She has refused to be lulled and stupefied by the warm, debilitating, heated air of the Americans, or stewed or half baked in the Dutch-oven-warmed atmosphere produced by the Continental plan. These investigations show that, in principle, she is right. The defect arises from the difficulty of carrying out the principle in all cases. But here, in this country, we have that rapid and most astonishing development of the gas interest which has carried the gas, comparatively speaking, into every nook and corner of every inhabited room in the kingdom. This was done primarily for the purpose of supplying light; but we are just discovering that this same gas is the best agent for cook-

ing. And, to add another valuable point to the already great popularity of gas, we see here the possibility of utilizing this agent for securing the very highest results in affording a wholesome and cheerful warmth with the purest air in any and every part of our occupied apartments. Of course, this subject of heating by gas is quite in its infancy. It is hardly to be expected that the first few experiments should have proved an entire success. But the demonstrations already made are certainly sufficient to prove to any intelligent engineer that gas offers the most perfect medium for accomplishing these most desirable results.

It will, however, require a considerable amount of demonstration to convince the ordinary customer who has not the time, inclination, or money to spare for experimenting, to prove these things for himself. But as the gas companies have already been greatly encouraged by the efforts they have initiated to demonstrate to the people the incomparable value of gas for lighting and cooking, I believe that, by an intelligent, energetic, and united effort on the part of the companies, they would soon be richly rewarded by the almost universal acceptance of this agent for warming and ventilation; and they would then earn the gratitude of their many millions of customers by supplying them with the means of using, and, in addition, teaching them how to use this universal and easily-supplied agent, so as to give them genial, wholesome warmth and pure air, all over their house. The great nightmare which weighs so heavily upon the sanitarian—the smoke that hangs in such depressing clouds over our great cities—would then disappear, and the bright, genial, unobstructed rays of the sun would bathe and purify our towns; and instead of an increased death rate appearing on the approach of cold weather, the well-regulated and comfortable temperature of our houses, taken in connection with the cold, bracing and external atmosphere, would give strength, vigour, and happiness to the young and old alike.

Discussion.

The PRESIDENT said Mr. Leeds came from America, where the science of ventilation was, he believed, much better understood and more generally applied than in England. He was sure the members would return him a vote of thanks for his paper.

Mr. C. R. MEAD (Sutton) said that his experience in gas matters extended for a period of more than 50 years, during which time he had seen many experiments on the subject of heating and ventilating; and he ventured to say he had seen one of the best warmed and ventilated houses in the world. This house was occupied by the late Mr. Appold—of rotary-pump notoriety—and was situated in Wilson Street, Finsbury. In or about the year 1848, he (Mr. Mead) had the pleasure of visiting Mr. Appold, and having the mode of warming and ventilating explained. Mr. Appold said that the first thing he did was to have all the floor-boards taken up, and a number of holes made through the neutral axis of the joists, so as to get a passage between the ceilings and the floors above them, by which the warm air might have a free flow. He then had air conductors so arranged that one set should convey the warmed air where required, and another set take off the vitiated air from the room. Having done this, he had the floor-boards relaid, and perforated with thousands of small holes, so as to allow the warmed air to pass up through them, and the carpets over them, into the rooms. In the basement of the house, he had a large gas-stove with an air chamber for warming, without burning the air. This air chamber was furnished with an inlet-pipe, to admit air from a yard at the back of the house, and an outlet-pipe to convey the warmed air to the air conductors in the house. The inlet-pipe was furnished with a large screen made of bunting. This sifted the soot and dust from the air; while a second screen, the bottom of which dipped into a tank of water, slightly moistened the atmosphere passing to the stove. He desired to have the temperature of the rooms at 65°; and the hall and staircases at 56°—the latter being high enough when people were moving about. The regulation of the temperature was managed by the action of a large and ingenious thermometer fixed in the middle of the house, and operating on a very delicate gas-valve, by means of which the supply of gas to the stove was regulated. Mr. Appold, like other inventors, found that air would not always travel as theory provided it should; and to get over the difficulty, he employed a steam-engine, by which he could drive either warm or cold air into the rooms, or exhaust the vitiated air. Mr. Appold had some difficulty with his dining-room, as the temperature rose very fast after the guests had been in the

room for a short time. To obviate this difficulty, he had a pedal arrangement under the table and an ornamental thermometer on the table in front of him; and if the room was getting too warm, he had only to press a pedal with the left foot, and cool air was admitted, passing quietly up through the carpet all over the room, until the proper temperature was restored. On the other hand, if from any cause it fell too low, the pressure of the right foot on another pedal admitted an extra supply of warm air. The whole theory of the business was that warm air should be passed into the rooms all over the floor surface, so that there should be an even temperature throughout the rooms, and that the vitiated air should be carried away through openings in the ceilings; such openings being furnished with properly exhausted air channels. There was only one matter Mr. Appold was not satisfied with, and that was the cost of gas, which, in those days of high-priced gas, amounted to from £9 to £20 per month.

Mr. JOHN CHAPMAN (Harrow) said the papers under discussion were both excellent ones. He regretted, however, there was not time to discuss them; and he feared the consideration of them would have to be left until next year. In his opinion, there was nothing so comfortable as to have a well-ventilated and well-warmed room.

The PRESIDENT said unfortunately there were so few members present, that he feared there would not be any further discussion; and he would ask Mr. Somerville to reply.

Mr. SOMERVILLE said he had only to answer the President's question with regard to Bunsen burners. He did not recommend them; he only mentioned them. On the contrary, he recommended a white-flame burner, because he always found it most difficult and almost impossible to prevent smell from a Bunsen burner. All he said was that if Bunsen burners must be used—some people would have them—take care and have good ones.

Mr. LEEDS, referring to the system of heating the air and driving it into rooms, said that this was an old device. It was done at the Houses of Parliament, and a number of other places; but it came to the original proposition after all—that the air had to be warmer than the air in the room. His principle was to leave the air cold, while the heat was used for radiation. In America he had spent an enormous amount of time and money on the attempt to warm the air, and to get it to go where it ought to; but he had come to the conclusion that it was better to warm the floor.

MR. NEWBIGGING'S CANDIDATURE FOR ROSSENDALE.—A deputation, consisting of the Mayor of Bacup (Alderman Lees), Mr. R. Lord (of Rawtenstall), and Mr. G. Moon (late of Bacup), recently waited on Mr. Thomas Newbigging, C.E., Manchester, and handed to him the sum of £212 15s. 6d., being the balance of his late parliamentary expenses, as promised previous to his acceptance of the candidature.

NORTH BRITISH ASSOCIATION OF GAS MANAGERS.—The twenty-seventh annual general meeting of this Association will be held in the rooms of the Royal Philosophical Society, Glasgow, on the 26th and 27th inst., under the presidency of Mr. David Terrace, of Dawsholm. A good programme has been prepared for the business meeting on the first-named day; and if this is got through, the members will have well earned the recreation provided for them on the second. In addition to the President's Inaugural Address, papers will be submitted on the following subjects:—"Gas Burners for Photometrical Purposes," by Mr. G. R. Hislop, of Paisley (being a report on the remit on the subject of the "Best Standard Burner for Scotch Gas"); "A year's Experience in the Manufacture of Sulphate of Ammonia," by Mr. R. Cowie, of Tillicoultry; "Tar as Fuel for Steam-Boilers," by Mr. J. McCrae, of Dundee; "Automatic Gas Lighting," by Mr. G. Keillor, of Nairn; "Selling Gas," by Mr. J. McGilchrist, of Dumbarton; "Regenerative Furnaces for Small Works," by Mr. J. Smith, of Rosewell; and "Scrubbing, Condensing, and Washing Coal Gas," by Mr. W. Key, of Tradeston, Glasgow. The report of the Sub-Committee of the Murdoch Memorial Fund will be submitted to the meeting. The discussion of the above-mentioned subjects will be an excellent day's work; and after it is over the members will dine together in the "Royal Bungalow," at the Glasgow Exhibition. On the following day there will be an excursion to Loch Lomond and Loch Long. The party will travel from Glasgow, via Balloch, to Tarbet, on the former loch, where they will take luncheon. The return will be made from Arrochar, on Loch Long; proceeding via Dunoon (where the journey may be broken for a couple of hours for tea at McColl's Hotel, in the West Bay), to Craigendoran Pier, and thence to Glasgow, which will be reached in good time in the evening. It will be seen, from an advertisement which appears in another column, that this meeting, with its attendant pleasant excursion, is not confined to members of the Association and their friends, but that members of other Associations who are desirous of taking part in it can do so on applying to the Secretary, Mr. R. S. Carlow, of Arbroath.

Essays, Commentaries, and Reviews.

GAS AND WATER COMPANIES IN THE STOCK MARKET.

(FOR STOCK AND SHARE LIST, see p. 135.)

THE past week has been a bright and active one on the Stock Exchange, after a continued period of comparative stagnation. Prices everywhere are on the upward move; even the unfortunate American Rails seem to be taking the long deferred turn. Foreigners, too, are even a little higher than they were before—thanks to the absence of political alarms. Money remains easy; though it cannot be expected to get any easier. Thus, everything points to the probability of better prices all round. In the Gas Department several advances in quotations have been scored. Foremost, of course, comes Gaslight "A," which has several times marked 260. The reason of its upward move is not far to seek, when it is remembered that the Company, having reduced the price of their gas by 3d. per 1000 cubic feet from the commencement of this year, are entitled to increase the rate of dividend for the half year just completed by $\frac{3}{4}$ per cent. The secured issues are still in demand; and some of their debenture and preference stocks have advanced. South Metropolitan have been very quiet. The "B" has improved 3, as might be expected from its appearance the preceding week. It must not be forgotten that this Company will be entitled to declare a $\frac{1}{2}$ per cent. higher dividend next month. The reports and accounts of the two larger Metropolitan Companies will, therefore, be interesting. Nothing at all has been done in Commercial; but the old stock has recovered 1. Imperial Continental has remained steady, with buyers at 1 higher. Crystal Palace is 5 better, and with reason, seeing what it fetches at the Mart. Some of the minor undertakings have been active, especially Bombay and Monte Video. Their quotations, however, have not moved, though advances have been made in many issues, as detailed in the list at page 135. Water (excluding the more speculative foreign undertakings) has been very quiet; the bulk of business being in Lambeth issues. Most of the Companies, however, show some improvement in quotations. The daily operations were: Monday opened firm and promising. Gas business was mostly in Bombay and Monte Video. Gaslight "A" was quiet, but rose 1 $\frac{1}{2}$. There was a little doing in Water, at moderate prices. There was a shade more activity in Gas on Tuesday, and general firmness. Gaslight "A" rose 1 more; and South Metropolitan "B," and Brentford new, made a similar advance. One transaction in Water was all. Lambeth 7 $\frac{1}{2}$ per cents. rose 1; and the quotation of Southwark ordinary was drawn in closer. The general tendency to improve continued strong on Wednesday. Gas business was mostly in Imperial Continental, which rose $\frac{1}{2}$; and advances to the same extent were made in Continental Unions. Gaslight "A" was erroneously credited with an advance of 5 $\frac{1}{2}$; but in point of fact it did not move at all. The "C," "D," and "E," however, rose 1. Water was an absolute blank; but Lambeth 10 per cents. rose 1. Very little was done on Thursday in gas, except in Gaslight "A," which rose 2 $\frac{1}{2}$. South Metropolitan "B" improved 2; Commercial old, 1; and Crystal Palace, 5. Water had nothing to note. Friday's business in Gas was only moderate; but prices were excellent. British rose 1; but nothing was done in it. Lambeth Water was unusually active; but nothing else was touched. Chelsea and Southwark ordinary improved 1 $\frac{1}{2}$; and New River, 1. Gas was active on Saturday, especially Gaslight "A." The 4 per cent. debentures rose 2. Nothing was done in Water, except New River debentures, which advanced 1. Southwark ordinary had a further rise of 1 $\frac{1}{2}$.

ELECTRIC LIGHTING MEMORANDA.

REVOCATION OF THE GAULARD AND GIBBS PATENT—DIFFICULTIES IN THE WAY OF ELECTRIC LIGHTING AT BARNET—THE BOARD OF TRADE REPORT ON THEIR PROCEEDINGS UNDER THE ELECTRIC LIGHTING ACT—PROPOSED CHARGES FOR ELECTRICITY AT BRADFORD.

THE uncertainty of the law is strikingly exemplified by the case of the Gaulard and Gibbs patent, which has just been upset on the petition of Mr. Ferranti, after it has been before the public for years. Indeed, the patent dates from 1882; and during the past six years the Gaulard and Gibbs system has been exhibited and worked in public without any noteworthy expression of doubt of its originality. In fact, it was a great deal too original for a good many learned professors of physical science, who could not understand it, and consequently followed the fashion of their kind in condemning the principle of the invention at the same time that it was being made by Mr. Westinghouse the basis of the cheapest known system of electric lighting from central stations. It is rumoured that the real petitioners against Messrs. Gaulard and Gibbs were the Grosvenor Gallery Company, who are actually using their system under a licence, but who put Mr. Ferranti forward as the nominal plaintiff, with the idea that if the patent was annulled they would be able to escape payment of royalty. If this is the "true inwardness" of the matter, it has a somewhat unpleasant savour; but any sharp practice of this kind is regarded as right and proper in some varieties of business. The essential fact to be borne in mind, however, is that the Gaulard and Gibbs patent has been revoked; and the system of distributing electricity for lighting purposes by transformers disposed in connection with alternating currents of high tension has been thrown open to the world. It is remarked by the *Electrical Review* that this result will not have much effect upon the commercial prospects of electric lighting, because Messrs. Gaulard and Gibbs were always ready to grant licences for working their supposed proprietary system. The

reputation of the unfortunate patentees for ingenuity in devising, and perseverance in working it out under great discouragement remains; and it is certainly a pity that in the eye of the law all this was wasted, so far as the patentees' private interest is concerned, upon a device which was not patentable.

The proposed electric lighting of the town of Barnet is not yet an accomplished fact. Warned probably by the example of Leamington, Mr. Joel, the electrical contractor, has represented to the Barnet Local Board that the 16-candle incandescent lamps with which they had proposed to light the streets would not be likely to prove satisfactory. It is a remarkable thing that while common batwing burners consuming 5 cubic feet of ordinary coal gas per hour, and generally giving the light of from 12 to 14 candles, are considered quite sufficient for average street lighting, a nominally superior lighting effect from incandescent electric lamps is always a failure. In the case in point, Mr. Joel recommended the Board to have lamps of 32-candle power; but the suggestion seems to have opened the eyes of the members of the Board to the truth that street lighting by electricity is not altogether a settled business. It appears that Mr. Joel, whose name is well known in connection with electric light engineering, wanted to light Barnet with his own arc lamps; but the Board did not see the necessity for them, and preferred something more like the usual gaslight. Then Mr. Joel agreed to fix 16-candle lamps, as desired by the Board; but now he wants to double the nominal illuminating power of the lamps, for fear of a failure such as he admits to have occurred with similar lamps at other places. And he added point to his objections by refusing to sign the contract for the street lighting until the Board consented to meet his views in regard to this matter. After a good deal of discussion, and with much misgiving, the Board gave way to their electrician; and it now remains to be seen whether they will achieve their desire of getting a better light for their streets by means of electricity at a saving on the cost of gas.

The Board of Trade report for the past year upon their proceedings under the Electric Lighting Act has been issued; according to which the only application for a Provisional Order since the last report was that of the South Metropolitan Electric Supply Company, for permission to occupy the City and a select district of the West-end of London. After hearing the objections of several of the local authorities named in the application, the Board of Trade granted an Order restricted to the parishes of St. James, Westminster, and St. Martin-in-the-Fields, with Waterloo Bridge and a small portion of the Victoria Embankment. It may be remarked here that a Bill to confirm the Order was introduced into the House of Lords and read a first time last week; the Standing Orders having been suspended for this purpose. Five applications for Licences are recorded, of which only one, relating to Liverpool, has been granted; besides the Licence to the Kensington Court Electric Lighting Company, which was mentioned in the last report. It is probable that the next report of the Board of Trade upon this subject will contain more matter.

Considerable interest attaches to the Bradford Corporation experiment in electric lighting from a central station, as it will be the first venture of the kind in the United Kingdom, and the first concerning which full and reliable accounts are to be published. It is proposed to sell the current to subscribers either at a charge of 5d. per unit, with 10 per cent. on the cost of the meter by way of rental, or for an annual rental of 20s. per lamp of 16-candle power, irrespective of the hours of burning. This is supposed to be equivalent to gas at 4s. 2d. per 1000 cubic feet. It is rather noteworthy that while the Barnet Local Board flatter themselves that they will get electric lighting from a contractor at a saving on the cost of gas, the Bradford Corporation, who mean to do the work themselves, do not entertain any such vain hope. The Corporation are trying to make three years' contracts with prospective consumers; and they propose to lay the services to the doors of their patrons—leaving them to provide internal fittings—probably reserving the right of inspection.

PRESENTATION TO MR. SAMSON FOX.—Last Wednesday an interesting event took place at the works of the world-renowned Leeds Forge Company, Limited, in the shape of a presentation to Mr. Samson Fox, the founder and Managing Director of the undertaking, on attaining his fiftieth birthday. It was the outcome of a desire expressed by the heads of the departments (twelve in number) to celebrate the remarkable success of the concern, and to express in some tangible way their high estimation of Mr. Fox's personal character and exceptional qualities as an employer. The form of testimonial selected by the donors was a piece of silver plate, and an address beautifully inscribed upon a piece of Leeds forge boiler-plate. The piece of silver had a total weight of upwards of 23 lbs. The large oval of the plateau had, on its upper surface, four views of the Leeds forge engraved upon it, surrounding an appropriate inscription. There were also views engraved upon the plate, representing four of the principal operations in the manufacture of a Fox corrugated boiler-flue. The presentation was followed by a banquet, at which Mr. Fox, the members of his family, and a number of guests were entertained by the subscribers. This took place in a portion of the offices, which was appropriately draped and set out with plants. One special feature of the room was the lighting of it with the new water gas which the Company have been for some time manufacturing for their own use. The Leeds Forge Company are, it is stated, the first in this country to manufacture and adopt this kind of gas for illuminating purposes.

THE OBSERVANCE OF TYPE IN STRUCTURAL DESIGN.

ONE of the most important considerations that can engage the attention of a gas engineer, as of anyone else occupied in works of construction, is the extent to which the idea of a type can be carried out in his designs; that is to say, the degree in which conformity to a certain standard of character can be followed in the class of structures for which he is responsible. Although this consideration is so important, however, it is not invariably recognized as such. Many designers seem to go to work oblivious of the idea of a type; and others only confess the influence of this idea indirectly and incompletely in the repetition of a few characteristics of style, which serve no other purpose than that of enabling an observer to identify their work at the first glance. This latter tendency is rather a trick of design—or it might be described as a mark of individual taste—than real observance of type-forms. The way to distinguish between a trick of designing, which is often no more than a trade mark, and true observance of a type, is to notice in what the particular indications appear. When an engineer always finishes off the tops of his gasholder guide-columns or standards in the same style, or repeats without variation the same string-courses and window-heads in his retort-houses, that is a trick, or as it might be less invidiously called, a mark of individual taste. There is, of course, nothing objectionable in this habit, so long as the favourite design is not bad in itself. It soon becomes recognizable as the brand of a particular designer; so that one can declare from afar who is responsible for the work which displays it. The peculiarity of it consists, however, in its being manifested wholly or principally in superfluities, sometimes called ornaments. It is much easier to show fancifulness in ornament than to let a whole piece of work tell who designed it. Yet even the latter may be done without necessarily involving observance of type. Gas-holders, retort-houses, and other imposing structures, may bear the easily recognizable impress of their creator, and yet be so divergent from others of like origin that nothing approaching conformity to type can be claimed for them. Conformity to type, then, is something more than, as well as distinct from individual expressions of taste in designs of structures. It may be combined with this preference of designers for stock embellishments and trade-marks; but the presence of the one does not, as a matter of necessity, imply the other.

Regard for type should be one of the chief cares of a designer at the beginning of his career as a responsible constructor; but we do not say that he should start with his types rigidly fixed in his mind. It is rather of the essence of a true type that it should be evolved and developed as time goes on and experience ripens; but there must be something fundamental, like a firmly-held principle, to begin with, upon which the developments of the type can grow. Take, for example, the design for a gasholder and tank. The designer must have in mind certain data upon which his work is to be based. We speak only of work that is really designed, and not copied from somebody else's patterns. Here the underlying principles may be that the tank shall be built of the most suitable materials available on the spot, and that the ironwork of the holder and framing shall be of light, easily-handled pieces, comprising the smallest possible variety of sections, and these of the cheapest and most ordinary description. This is quite enough to constitute the leading idea of a type of gasholder construction. With the next opportunity the designer will be able to see wherein the plan may be modified, either out of regard for local conditions or to secure some general advantage; and the type will be yet more distinctly emphasized. So again with every subsequent repetition; the more the type is modified, the more will it be developed and maintained, so that in time men will be able to say "this is one of Mr. Blank's holders," not because of the appearance of a particular finial on the columns or rosette on the girders, but merely from the general conformity to type which they are able to recognize in the work itself. So long as the type is good, this is the highest praise that can be accorded to its creator.

The observance of type descends into much smaller matters than the design of a large structure; and within certain limits, it saves much expenditure of brain power on the part of the designer. In gas making, for example, the right shapes and dimensions of retorts constitute questions upon which much variety of opinion has prevailed, leading to a bewildering complexity of patterns and occasionally to much perplexity on the part of manufacturers. In France and Germany the inconvenience of this multiplicity of sections of retorts has led to the adoption of a few type-forms, which all constructors of retort settings will be bound to respect under penalty of having to pay extra for abnormal patterns. Whether anything like this formal agreement is possible among gas makers in general is doubtful. But it is evident that every engineer who entertains a preference for a particular shape and size of retort should be able to adduce sufficient reasons therefor; and for these reasons he may be expected to repeat this favourite design wherever the conditions are favourable to it. The same may be said of other points of design.

There is the question of the character of the gas-mains inside works. Some engineers have a liking for special castings, in the interest of perfect distribution, the reduction of friction in the flow of gas, &c., while others will not hear of anything but the most ordinary bends, tees, and junctions—letting the gas currents take care of themselves. One man is all for tees and blank flanges for clearing the mains of obstructions, another prefers the easiest of bends when the direction of the flow of gas has to be changed, providing an occasional manhole for inspection and cleaning. Indeed, it is more difficult to point out the details of gas-works

construction in which there is no scope for individuality of design, than to name those in which there is wide room for choice of methods of attaining the same end. We do not say that it is either necessary or desirable for every gas-works to differ in everything from others of the same size. Observance of type is a totally different thing from vainly striving after either originality or oddity of design.

Observance of type is something more than a preference for uniformity of pattern or dimensions; but it frequently finds expression in the latter. When a manufacturing firm have decided upon the type of machine which they intend to make their speciality, the next step is to settle the sizes and patterns in which it is to be made; and the fewer these are, the better. In the beginning of an industry, there is likely to be almost infinite variety in the product; but after the practical requirements of the trade have been sounded, these are cut down to a narrow range; which yet satisfies everybody. Electric lighting engineering in this country is now passing through this stage. Every large order that is given for an installation of incandescent lighting for a mansion or public building, entails a fresh design in the way of dynamos, switch-boards, or some other important fitting, with the necessary consequence that the work is long in hand, expensive, and difficult of repair. It argues a considerable experience of the necessities of an industry when the essential machinery is made to gauge, with interchangeable parts which can be replaced from stock at short notice. The types must be approved by theory and practice before their expression can be multiplied as it were automatically.

There is nothing like sameness or poverty of invention in a strict adherence to type. In the natural world, types are comparatively few, while modifications and developments for special purposes are innumerable. The rudest draughtsman that ever chipped the prehistoric flint or moulded the dateless clay, like him of the present who scribbles on a pavement with a piece of chalk, can indicate the type of a fish or of a man without observance of specific character or individual likeness. So in engineering; the type once established, there is plenty of scope for varying the design for special purposes without contradiction of fundamentals. If only the type is preserved, its modifications must be mutually harmonious and rational. It is when fundamentals are outraged in successive designs from the same hand that there is confusion, and the critic is driven to the conclusion that the designer does not know his business, and that any approach to rectitude of principle which may have been observable in his work is accidental. This is the worst reproach that can be brought upon a designer, and places him upon the level of a child who, playing ignorantly with a musical instrument, has by chance evoked a thrilling chord, only to follow it up with a nerve-shattering noise.

Therefore it is to be urged upon all designers that, in their capacity of creators, they observe, as one of the fundamental laws of their actions, that principle of conformity to type which is the highest expression of perfect skill and sanity. Eccentricity is sometimes striking; and the production of an unlooked-for effect, or of a commonplace effect by extraordinary means, is dear to a certain order of mind. But that is not the highest class of mind. Economy of effort, unity of aim, ease and certainty of execution, are all subserved by observance of type; and the recognition of a new type, the perception of what it is capable of developing into, is a task for the keenest and most original intellect.

THE EDINBURGH AND LEITH CORPORATIONS' GAS BILL.—As mentioned by our Edinburgh Correspondent last week, the Edinburgh and Leith Corporations' Gas Bill came before the Select Committee of the House of Commons, to whom it was referred as an opposed measure, on the 5th inst.; and, the opposition of the petitioners against it having been disallowed, it was formally passed on to the Committee on Unopposed Bills, by whom it was considered on Tuesday last. Mr. Beveridge presented the necessary proofs of the preamble of the Bill, and thereafter went through the clauses *seriatim* with the Committee. The examination of the Bill by the Chairman (Mr. Courtney) was very minute, and lasted a considerable time. At the close, the Bill was signed, and ordered to be reported. This, as shown by our "Parliamentary Intelligence," was done on the same day; the Bill being read the third time on Thursday. It now only awaits the Royal Assent.

THE GAS AND WATER INVESTMENTS TRUST, LIMITED.—In our issue of May 22 last (p. 917), we referred to the registration of a Company, called the Gas and Water Investments Trust, Limited, with a nominal capital of £3,000,000, divided into 600,000 shares of £5 each. We now learn that a strong Board has been formed, and that the first issue of the capital of the Company will shortly be offered to the public. The objects of the Company will be similar to that of other trust companies recently formed; the only difference being that gas and water investments will be made a speciality, and that the Company will guarantee the issues of the mortgage debentures of new and approved gas and water undertakings. The shares of all the recently formed trust companies have been eagerly applied for; and the public estimation of such securities as an investment may be judged by the fact that these shares cannot now be obtained at less than from 10 to 30 per cent. premium. Assuming that the Board of the Gas and Water Investments Trust, Limited, consist of men of the necessary experience and position, and possessing public confidence, we do not see any reason why this Company should not be as successful as those to which we have referred. The Secretary is Mr. J. A. Kellman.

Notes.

RECENT TESTS OF THE WELSCHACH BURNER.

In the course of a report by Professor Henry Morton, of the Stevens Institute of Technology, of Hoboken (N.J.), on some tests made by him of a number of Welsbach burners which he has had in use in his house since the beginning of this year, he gives the following results, which he says have been constantly duplicated with a large number of burners:—

Burner.	Pressure in Inches.	Consumption in Cubic Feet.	Candle Power.
No. 1. ..	1.01	2.25	25.5
No. 1. ..	0.90	2.10	25.5
No. 1. ..	0.80	1.95	24.0
No. 2. ..	1.00	2.30	23.0
No. 3. ..	0.85	2.45	24.0
No. 4. ..	0.95	2.75	33.0
No. 4. ..	0.80	2.47	29.0

The efficiency and economy of these burners, as compared with the standard Argand, will be seen when it is stated that the same gas, consumed with one of the latter burners at a pressure of 8-10ths of an inch, and at the rate of 4 cubic feet per hour, gave a light of 16 candles, or 4 candles per cubic foot; whereas with the Welsbach burners, the lowest result was about 10 candles, and the highest 12 candles per cubic foot. The following results were obtained by Dr. L. Calvert Ford, the Government Inspector of Gas and Meters at Washington, in the course of some tests made by him at the request of Mr. G. A. McIlhenny, of the Washington Gaslight Company (the standard burner, with a consumption of 5 cubic feet per hour, giving 17.99 candles):—

Pressure at the Point of Ignition, in Inches.	Consumption per Hour, in Cubic Feet.	Actual Candle Power.	Value per Cubic Foot in Terms of Standard Candle.
6 tenths ..	2.14	17.01	7.94
7 " ..	2.19	18.42	8.41
9 " ..	2.78	22.65	8.14
10 " ..	2.82	24.11	8.54
13 " ..	2.92	24.95	8.54
Average . . .	2.57	21.42	8.21

The increased illuminating power obtained with the Welsbach burner was found to be equal to 19 per cent., with a saving in consumption of upwards of 48 per cent.

THE PARIS MUNICIPAL DUTY ON ILLUMINANTS.

In a recent number of the *Revue Industrielle*, M. Delahaye shows the amount of *octroi* and municipal dues paid by different illuminating materials employed in Paris. The chief of these are candles, vegetable oil, mineral oil, and gas. The candles principally used are sold in fives and sixes to the packet; the former giving a light of 0.136 carcel, and the latter of 0.131 carcel, with a mean hourly consumption of 10 grammes of stearine. It therefore requires 7.4 of one size of these candles and 7.6 of the other to give the light of a carcel-hour. The mean duty on this is 0.018 fr. The carcel-hour as afforded by colza oil lamps pays 0.0137 fr. duty. With mineral oils the rate of consumption to lighting effect varies greatly with different patterns of lamps; but according to Mr. Boverton Redwood, a consumption of 3.23 grammes should give a candle-hour. Taking the carcel at 8.91 candles, the consumption for a carcel-hour would be 28.77 grammes. For reasons given, M. Delahaye places the average lighting value of petroleum at 35 grammes per carcel-hour. This means an *octroi* of 0.0094 fr. per carcel-hour. The gas sold by the Paris Company, is subject to a variety of imposts, which may be calculated in different ways according to the manner in which they are regarded and the various allowances reckoned. In this way the *octroi* on the carcel-hour by gas may appear to be either 0.0109, 0.0046, or 0.0026 fr.

THE SUSTAINING POWER OF SOILS.

In a paper read before the Civil Engineer's Society of St. Paul (Min.), Mr. Randall Hunt dealt with the supporting power of soils; and specially referred to the treacherous nature of clays, which, as a rule, are hard enough in dry weather, but have the capacity of retaining water once admitted, and becoming softer and softer as the quantity of moisture is increased. It appears from the examples cited by Mr. Hunt that the load on a pure clay foundation should not exceed from 1½ to 3 tons, according to the nature of the clay and the possibility of keeping it tolerably dry. When clay is mixed with other materials, such as coarse sand or gravel, its supporting power is usually considerably increased, becoming greater in proportion with the other materials, up to the point when the mixture forms a mass like natural concrete, in which the clay is the cementing material. Such subsoils will bear loads like the softer rocks. Foundations on coarse sand and gravel are usually successful, in the absence of running water. Loose fine sand may be rendered more fit for building on by ramming in thin layers. The limit of safe loading upon the sandy soil of Berlin is taken at about 2.3 tons; but it has been successfully loaded up to 4.1 tons per square foot. With soft alluvial soils it is found that the supporting power of the soil is greater in proportion as the loaded area is limited; or, conversely, large areas of soft soil will not support as much weight per unit of surface as more limited areas of the same soil.

PETROLEUM v. GAS-ENGINES

In a report upon the Priestman petroleum engine, Sir Samuel Canning and Messrs. H. Alabaster, Gatchouse, and Co., instituted a direct comparison between the working expenses of an engine of this kind and a gas-engine. Priestman's engine consumes common

refined petroleum or kerosene, of about '800 specific gravity, now costing 6½d. per gallon. A 6-horse power engine was selected for the purposes of the trial; giving actually 6·488-horse power on the brake. The consumption of oil with this engine was after the rate of 10·8 pints per hour, or 1·68 pints per brake horse power. It therefore appeared from this test that the cost for oil alone per actual horse power with this engine was approximately 1½d. per hour. The maintenance of the galvanic battery which, by the aid of an induction coil, ignites the explosive mixture in the cylinder of the engine will cost about 2½d. per day of nine hours. Very great stress is laid upon the fact that the makers of this particular pattern of petroleum motor have succeeded in using the ordinary petroleum of commerce, instead of the troublesome spirit which is used for all other engines of the same kind. This is a great advantage, since petroleum oil may be obtained and stored anywhere, without a licence, which is not the case with the spirit. There is little or no residuum with the Priestman engine. The running of the machine is also very regular; and there is no dirt. There is no necessity for oiling the piston; the oily vapour supplying all the lubrication required. It is concluded that these engines can compete favourably with gas at anything over 3s. 6d. per 1000 cubic feet, and they are declared to be suitable "for isolated electric light installations, and even larger operations of the kind, and for every use to which gas-engines can be put; with the special advantage of being capable of employment where gas cannot be utilized."

Communicated Article.

THE SYSTEM OF MONTHLY COLLECTIONS BY GAS COMPANIES.

By A MANAGER ABROAD.

I glean from the papers that come to me by each succeeding mail that the question of which is best—weekly, monthly, or quarterly collection of accounts, is at present agitating the minds of gas managers at home; and several managers having referred to the fact of the system of monthly collections being in existence on the Continent and abroad, and the system being in use on the works of which I am Manager, I thought perhaps I could help my brother managers in forming an opinion on the subject, by laying before them a few of what I consider to be the advantages and disadvantages of the system. At the same time I would say that while writing I have in my mind a works of medium size—say, of from 40 to 50 millions per annum—and that readers may draw their own conclusions as to the advantages or disadvantages of extending the system to works of a larger output.

Taking the generality of gas company's consumers, it will be found that they may be divided into three classes—first, the artisan class, who are paid weekly; secondly, the middle class, paid monthly; and, thirdly, a small majority of the upper class, paid quarterly. In the first case it may be well to consider how far an alteration in the present system would affect these different classes. In regard to the artisan class, it would undoubtedly be a great advantage to the consumer if the system of weekly collection could be adopted and carried out, for, under the present system of quarterly collection, it is easy to imagine what a small percentage of the whole body would at the end of the quarter have laid aside out of their weekly earnings enough money to pay a quarter's gas bill; and as long as the present quarterly system is carried out it will be useless for a gas company to think they will make consumers of the general body of the artisan class. On the other hand, a weekly collection would be a great inconvenience to the middle class, who are paid their salaries monthly, and rather a trouble and useless annoyance to the higher class and the majority of tradespeople. We therefore come to consider the question of a monthly collection. Now, the majority of a gas company's customers are of the middle class, and among the tradespeople; and of these, the former are, as a rule, paid their salaries monthly, while the latter usually settle their accounts monthly. It would therefore be manifestly to the advantage of these two classes of consumers if they could pay their gas bills monthly instead of quarterly. As affecting the artisan class, it would still be out of the reach of some, but at the same time much nearer their grasp than the quarterly system; and by adopting this system, the company would undoubtedly find some fresh consumers among this class. As regards the higher class, I do not think they would suffer any disadvantage by the change from a quarterly to a monthly collection; and a collector soon gets to know those who prefer to settle quarterly, and acts accordingly. With respect to quarterly collection, the only thing to be said in its favour is that it is "old custom;" for it cannot be pointed out as a benefit to the majority of any one of the classes above named. As for the first, it puts gas completely out of their reach; the second forget all about the gas, and at the end of the quarter find the bill so high that it is a great strain on their last month's salary (for in these days of low salaries, how many of the middle class live almost from hand to mouth); while to the third class it is a matter of indifference.

Having dealt with the various systems as affecting the different classes of consumers, it remains to be decided which is the best of the three; and I think my readers will agree with me when I say that the plan of monthly collection appears to be the best for the large majority of the consumers. Each system having its advantages, it may be asked why not adopt all three? But I believe this would only tend to confusion; and, therefore, on the principle

of "the greatest good for the greatest number," I incline to the general adoption of the monthly arrangement.

It will now be for me to deal with the matter as affecting the gas company, but referring directly to the monthly system, which I have already proved to be to the advantage of the consumer. I will therefore, as briefly as possible, point out some of the advantages to be derived from this system of collection. In regard to security, the accounts being smaller, and collected more frequently, the present amount of security may be considerably reduced; for, as is well known, the question of security has frightened many a would-be consumer. For the reason here given there will be fewer bad debts at the end of the year. If from the weather, or any other cause, the gas bills should suddenly increase considerably, a manager, inspector, or collector has a much better chance of being able to explain the reason to a consumer at the end of a month, than if he had to wait for three months, when the occurrence would probably have been forgotten. A greater check is kept on the meters; and if they should get out of order and stop registering (as they will do), it is much better, for obvious reasons, that this stoppage should be discovered within one month than in three months. Monthly collection, bringing the manager, collector, and inspector more regularly and frequently in touch with the consumers, will tend to create more confidence between the latter and the company's officials than exists at present. With a proper system of books, the accounts should be all ready and in the hands of the collector within three days of taking the indices. Everything is kept up much closer, and work in the office is greatly facilitated by the books being made up monthly instead of quarterly and half yearly, at which latter time there is always a quantity of extra work in preparing the half-yearly returns. Each month it would be extremely easy for the manager to investigate the results of his month's working, leakage account, &c., and with each month made up, the work at the end of the half year would be considerably lessened. The company would undoubtedly be benefited by an increase in the number of consumers, owing to the proposed easier mode of payment.

The foregoing are some of the advantages which I consider would be brought about by an alteration of the present system of collection. But I would also put against these the only two serious objections to the alteration. (1) There would undoubtedly be additional work thrown on the office staff. But the employment of an extra clerk would quite overcome this difficulty; and after a time the work would take such a routine form that no difficulty whatever would be discovered in working the system. Again the cost of an extra clerk would soon be compensated by the increase in business and the decrease in bad debts. (2) Extra work on the collectors. I must admit that these long-suffering fellow-mortals would have more work to do. But even with them the system would have an advantage, for they would encounter less grumbling; and, the bills being smaller, there would be much more likelihood of their being paid than the collector hearing so many requests of "Please to call again."

The gas accounts being sent out monthly, to be consistent it is necessary that all the sundry accounts should also be sent out monthly; and for this purpose I divide the sundry accounts into two classes—residuals and gas-fittings. The number of accounts in the former class are so few that it is quite possible, and even necessary for making up the month's return, that these should be got out at the close of each month. I find, in regard to gas-fittings accounts, that it is desirable they should be in the hands of the collectors, to allow of their being presented at the same time as the gas bills; but it will be found almost impossible, without a large staff, to get the gas-fitting accounts ready by the third or fourth day of the month. Therefore adopt the plan of making out (say) April accounts towards the latter end of May, when work is a little slack. I then have them checked and signed by the end of the month, ready for the collector when he receives the gas bills. I may say that a long experience of this has quite convinced me of its efficacy, both in working of books, and also in collection.

By the foregoing remarks I think I shall have proved to my brother managers the desirability of adopting the system of monthly collections; and they will see, I think, from what has been said, all the advantages that would attach to the system. Of course, I am aware that it means a radical alteration in the existing state of things, and will not at first be so easily carried out in England as it would in a foreign country. But I am sure that, after a little experience of the system, its conveniences and advantages, both to the company and consumer, will become so apparent that they will not fail to justify such a reform. Gas companies are so threatened at the present time, on the one hand kerosene, petroleum, &c., that it is absolutely necessary attention be paid to the requirements of the consumer, and if, without serious loss, means can be devised by which the charges on a gas consumer may appear lighter, then it is the duty of the company to adopt such means.

At their first meeting on Monday last week, the new Council of the Society of Arts elected the Duke of Abercorn, C.B., as Chairman for the ensuing year.

The Toulouse Gas Company have just completed an electric light installation for the Théâtre du Capitole; the current being supplied by two 500-light dynamos driven by a 50-horse power "Otto" gas-engine. There are 1000 lamps (fixed on two independent circuits), varying from 10 to 20 candle power; and these are said to give a very satisfactory result.

Technical Record.

THE ASSOCIATION OF MUNICIPAL AND SANITARY ENGINEERS AND SURVEYORS.

The Annual Meeting of this Association was held on Thursday, Friday, and Saturday last week, at the Institution of Civil Engineers, Westminster, S.W., under the presidency of Mr. E. B. ELLICE-CLARK, M. Inst. C.E.

The formal business having been disposed of, on the first morning of the meeting, the President delivered his Inaugural Address, in which he stated that there had been a greater increase in the number of members during the past year than in any year since the formation of the Association. He advocated the combination of private pupilage with study at some technical school as essential to the proper instruction of municipal and sanitary engineers. Alluding to the work yet to be done by the latter class, he said, judging from his own professional experience, that there were 375,000 houses, of over £100 annual value, in London alone, where new drainage works were absolutely necessary. The same condition of things obtained in a greater or less degree in all provincial towns. There was also much to be accomplished in connection with the arterial drainage of towns and the prevention of floods in the great river valleys. In spite of all that had been accomplished within the last 40 years, the sanitary condition of towns was still incomplete. Referring to air pollution by smoke, he remarked that, owing to the cheapness and availability of fuel in this country, the method of obtaining heat in dwelling-houses was only one step removed from the consumption of fuel in an open hearth in the tent of the savage. The same unscientific method of producing heat prevailed (only in a less degree) in nearly all factories in the country. Thus one-half of the effective value of fuel was wasted; and the air was polluted so as to make it, throughout a considerable portion of the year, in most cities, almost insupportable. London fog, which was such a nuisance in the winter, was largely due to the unconsumed carbon caused by smoke, from domestic fireplaces. The future municipal engineer must therefore, among other things, pay attention to the prevention of air pollution by smoke. No doubt considerable advances had been made in this direction; but, in his judgment, an attempt to overcome the difficulty by burning fuel in an open stove would end in failure. They were nearer to a solution of this matter than was generally supposed. The manufacture and distribution of non-luminous gaseous fuel, for heating purposes, from a central station he believed was not very far distant. By this means, they would not only prevent air pollution by smoke, but would be able, in a very large degree, to overcome the difficulty of removing the decaying matters not passed into the sewers. If such a system were at work in any town, there would, of course, be few or no cinders or ashes to be removed from houses; and there should be no difficulty in designing such a stove, fed by gaseous fuel, as would in every house consume the decaying matters which now formed so large a bulk of "house refuse." In his concluding remarks, he advocated a State College or Permanent Commission for original scientific research; and maintained that enormous sums would have been saved if even only the disposal of town sewage had been dealt with by such a competent body.

The reading and discussion of papers afterwards occupied the attention of the members; one of them being by Mr. G. R. Strachan, of Chelsea, on "The Average Meter System." The full text of this paper, with the discussion, will be found in another column. At the conclusion of the paper, the members adjourned to inspect the drainage works at the Houses of Parliament, where the Shone system is in use. The reading and consideration of papers was resumed on the following morning; the first one, by Lieut.-Col. Jones, V.C., dealing generally with the Shone sewerage system. This communication consisted mainly of the author's experience of the system during the past ten years, and also of particulars in regard to its adoption at various places; prominence being accorded to Henley-on-Thames, where he said the system was perhaps more fully carried out than in any other instance of its application yet completed. An exhaustive discussion followed, which, taken on the whole, was very adverse to the system. One speaker thought that it had "merits in a limited sphere and for limited ends;" and again, in reference to the Shone works at the House of Commons, it was stated that though they "were the most beautiful and the cleanest sewage works in the United Kingdom, they stood unique in being the most expensive." The President, referring to the operation of the works at Henley, mentioned that he was there for two or three days in the previous week, and, to use his own words, a more "stinking town" than Henley-on-Thames he had never met with. Another interesting paper was that by Mr. W. Webster, on "Sewage Purification by Electrolysis," in which the author gave a full and explicit statement as to the working of his system; and also made some interesting experiments with water containing sewage, which showed that, after a few minutes' treatment, the particles of sewage rose to the top of the water, leaving the bottom part perfectly transparent. A paper by Mr. W. Santo Crimp (who was unavoidably absent), on "Water Supply," was taken as read. We hope to give portions of this paper on a future occasion.

In the course of the afternoon of Friday, visits were paid by the members to the Lucifon light works, and to Brien's oxygen works (both at Westminster), and afterwards to the Battersea Bridge works. On Saturday, a trip was made down the river, to inspect the Tower Bridge, and the new sewage outfall works at Barking.

MR. VERNON HARCOURT'S NEW PHOTOMETER.

Our readers will remember that in the notice of the first *soirée* of the Royal Society for the present season, which appeared in the JOURNAL for May 15 last (p. 862), brief reference was made to the new photometer devised by Mr. A. G. Vernon Harcourt, called the holophotometer, which was exhibited on the occasion by the makers, Messrs. Woodhouse and Rawson, Limited. In the following issue (p. 911), we gave some particulars of the instrument; at the same time promising an illustrated description of it in a future number. We are now, through the courtesy of the Editor of the *Electrical Review*, in a position to redeem this promise; he having kindly permitted the use of the following illustrations of the photometer. Fig. 1 is a view of the instrument from behind, showing the divided scale; fig. 2 is a view taken from the end of the photometer-bar, showing how the horizontal light from the lamp is transmitted to the disc; and fig. 3 is a view taken looking from the disc, and showing how the vertical light would be transmitted to the disc. In order that the illustrations may be perfectly understood, we reproduce the descriptive matter which has already appeared in our columns.

FIG. 1.

The holophotometer has been designed in order to get rid of two difficulties connected with other methods of attaining the same object—viz., to measure the light emitted in every direction by any luminous source. These difficulties are: (1) The movement of the light to be measured or of the standard lamp, neither of which is desirable. (2) The errors caused in the measurement of lamps provided with reflecting fittings, by the assumption that the flame is the zero point from which measurements should be made, whereas, strictly speaking, the principal focus formed by the reflector should be taken as the zero point. Inasmuch, then, as this focus may be several inches away from the flame, and as the length of bar usually employed is 60 inches, it is evident that serious errors may be introduced by the difference between the real and the assumed zero point.

To establish the existence of such an error, and to eliminate it, two things are necessary—viz., that readings should be taken with bars of various lengths; and that the length of the bar should be very great compared with that between the real source of light and the focus formed by the reflector. Both these points are secured by the use of the holophotometer. The instrument is mounted upon a table capable of being moved nearer to, or further from, a

FIG. 2.

FIG. 3.

fixed table containing a graduated bar with moveable disc (say of the Lethby pattern), and having a standard lamp fixed at the zero of the bar. The lamp to be measured is mounted upon, or is in rigid connection with the moveable table, and is therefore not moved during a series of readings.

The holophotometer consists of an axis working friction-tight in a collar supported by a vertical pillar. The axis is accurately fixed at the same height, and in a line with the centre of the disc. At the end nearest to the disc is placed a large mirror, with its centre concentric with the axis, but so arranged that the plane of the mirror may be inclined and clamped at any angle to the axis. At the other end of the axis is fixed a telescopic arm, carrying a smaller mirror, which is capable of being turned into any required position. The arm being rigidly fixed to the rotating axis of the instrument, to which is also attached the larger mirror, it follows that the rotary motions of the mirrors about the axis are identical. The angles of rotation are measured by the indications upon a divided circle attached to the moving axis, which are shown by a pointer fixed to the upright support.

The mirrors are adjusted in such a way that the light from the lamp to be measured falls upon the smaller mirror, thence is reflected on to the larger one, and finally along the axial line of the photometer disc. As both mirrors rotate together, it follows that if a horizontal beam is reflected correctly, all other beams will find their way along the axis of the photometer. If, therefore, the arm carrying the small mirror be moved through various angles, it will receive the light emitted from the lamp at those angles, and the light will at every angle be transmitted along the axis of the photometer. The divided circle is made large enough to serve as a

complete screen of all direct light; and only the light falling on the small mirror can find its way to the disc. In order that absolute, as well as comparative, tests may be carried out, only one additional measurement need be made. The direct horizontal light is measured without the interposition of the holophotometer (which is mounted so as to be easily moved out of the direct line); then the mirrors are interposed, and a new measurement made. The additional path travelled by the light is allowed for in calculation; and thus the absorption of the mirrors is found once for all for the particular character of light under measurement. It is only necessary afterwards to multiply subsequent values by this coefficient of absorption, in order to obtain absolute measurements at various angles.

The employment of mirrors in photometry has sometimes led to serious errors; but it will be seen by the foregoing description that inasmuch as the relative angle of the mirrors is never changed, and as their absorption is easily calculated and allowed for, the only objections to their use have been guarded against and avoided.

In order to eliminate the second source of error mentioned above—viz., that arising from the formation of a principal focus—it is only necessary to take a series of readings with the table in one position, and then move it to a greater distance and take another series. If a focus is formed at a sufficient distance to produce an appreciable error, it will clearly appear in the difference between the readings at the two distances; and then it is only necessary to wheel the table to such a distance that the discrepancy is inappreciable. In other words, this is equivalent to using a bar of sufficient length to make it practically infinite compared with the distance between the focus and the real source of light.

The instrument has been designed specially for use in light-house work, where it becomes of the highest importance to measure accurately the total light given by any lamp, and not only that emitted in any one particular direction, which may or may not be the maximum.

Preliminary experiments made with the instrument by Mr. Stepney Rawson, at the works of the Woodhouse and Rawson Electric Manufacturing Company, have shown what a valuable instrument it is for the determination of the commercial value of various lamps, as well as for assisting in the many difficult problems of the diffusion and reflection of light. The absorption of the two mirrors used is as already mentioned, stated to be only 1·8 per cent.; but a series of experiments are to be made on this point.

THE AVERAGE METER SYSTEM.

By GEO. R. STRACHAN, Assoc. M. Inst. C.E.,
Surveyor to the Chelsea Vestry.

[A Paper read at the Annual Meeting of the Association of Municipal and Sanitary Engineers and Surveyors.]

The writer has been experimenting with regulator gas-burners for some eighteen months, with a view to ascertain their reliability under various and varying pressures and conditions; and in the course of the experiments, doubt has been raised in his mind as to whether the average meter system is necessary to a reliable and economical determination of the volume of gas consumed in the public lamps. His object in bringing the subject before the Association is to obtain the criticism of the members on his conclusions, in order that the true system may be revealed.

The average meter system, as practised in the Metropolis, is briefly as follows:—Each lamp is provided with a regulator gas-burner which passes a definite quantity of gas per hour under the varying pressures in the mains; and at certain lamps (carefully selected by the gas company and the local authority) meters are fixed which record the volume of gas burned. Each month the meters are read; and, after striking out the returns of those which show a variation of 10 per cent. over or 10 per cent. under the theoretical volume obtained by multiplying the number of hours during which the lamps were lighted into the cubic feet per hour to which the burners are set, an average consumption is obtained for the selected lamps, and this is taken as the consumption for each lamp throughout the district. The question raised is: Are the regulator gas-burners sufficiently accurate to be relied upon for the quantity burned without the check of the meters?

In the following experiments an experimental gasholder and minute-clock by Parkinson were used. When the burner experimented on was fixed over the meter, it was not removed until the experiment with it was completed. In each experiment the gasholder was filled with 5 cubic feet of gas, and was not refilled during the time, so as to secure, as far as practicable, gas at the same temperature and barometric pressure. The increase of temperature in the gas by the increased pressures is common to all the experiments; so that they give a basis of comparison when this slight error is neglected. The water-gauges on which the pressures were recorded were four inches below the regulators. The regulator gas-burners experimented on were bought in the open market without the knowledge of their makers, so as to avoid specially prepared burners; and it is possibly due to this that the results obtained present discrepancies. The names of the makers are not stated in the paper, as the writer does not approve of using the platform of the Association as an advertising medium. The aim of the tests was to find out whether the regulators controlled the consumption of gas under varying pressures at the volume to which they were fixed. The pressures given are water-pressures; thus, 1 inch is 10·10ths pressure, &c.

Experiment 1.—The burner used was a 5-feet fishtail common burner, said to be a "regulator," but possessing no regulating

apparatus whatever. The figures under the pressures give the number of cubic feet per hour :—

	PRESSURES IN INCHES.							Averages.
	1	1·5	2	2·5	3	3·5	4	
A	7·12	8·85	10·70	11·55	12·82	13·52	14·55	11·30
B	6·55	7·67	10·12	10·82	12·00	12·65	13·30	10·44
C	6·58	7·86	10·17	10·75	11·85	12·95	13·87	10·57
Averages	6·75	8·13	10·33	11·04	12·22	13·04	13·91	10·77

These results show that the burners are not regulators. The vertical column of averages shows the greatest variation to be 7½ per cent. The horizontal column of averages shows that the burners at 1 inch pressure passed 35 per cent., and at 4 inches pressure 178 per cent. more gas than they were marked to do.

Experiment 2.—The burner used was a 6-feet batswing common burner, said to be a “regulator,” but possessing no regulating apparatus whatever :—

	PRESSURES IN INCHES.							Averages.
	1	1·5	2	2·5	3	3·5	4	
A	8·87	11·05	12·87	13·77	14·77	16·25	16·70	13·47
B	7·70	10·03	11·50	12·75	14·10	14·95	16·22	12·46
C	8·40	10·85	12·20	13·20	14·52	15·50	16·55	13·03
D	9·38	11·52	12·42	13·65	15·00	16·10	17·90	13·71
Averages	8·59	10·86	12·25	13·34	14·60	15·70	16·84	13·17

The vertical column averages show the greatest variation to be 9 per cent., the horizontal column averages show that at 1 inch pressure the burners passed 43 per cent., and at 4 inches of pressure 181 per cent. more gas than they were marked to do.

Experiment 3.—The burner used was a 5-feet public lamp regulator burner, with a regulating apparatus :—

	PRESSURES IN INCHES.							Averages.
	1	1·5	2	2·5	3	3·5	4	
A	5·82	5·51	5·55	5·47	5·36	5·16	4·98	5·41
B	5·33	5·30	5·23	5·17	5·08	4·85	4·60	5·08
C	5·43	5·47	5·31	5·15	5·05	5·03	4·85	5·18
Averages	5·52	5·43	5·36	5·26	5·16	5·01	4·81	5·22

The vertical column averages show the greatest variation to be 6 per cent., and indicate carelessness in manufacture. The horizontal column averages show that at 1-inch pressure the burners passed 10·4 per cent. more, and at 4 inches of pressure 4 per cent. less gas than they were marked to do, or a total variation of 14·4 per cent. They also show that the regulating apparatus checks the waste of gas at increased pressures, but that the volume of gas passed falls off gradually as the pressures increase.

Experiment 4.—The burner used was a 4-feet public lamp regulator burner, with a regulating apparatus :—

	PRESSURES IN INCHES.							Averages.
	1	1·5	2	2·5	3	3·5	4	
A	4·27	4·57	4·47	4·48	4·45	4·47	4·47	4·45
B	4·18	4·35	4·37	4·32	4·25	4·35	4·36	4·31
C	4·33	4·43	4·50	4·40	4·41	4·40	4·37	4·41
D	3·95	4·06	4·11	4·32	4·22	4·06	3·87	4·08
E	4·30	4·31	4·29	4·32	4·28	4·30	4·12	4·28
F	4·31	4·35	4·40	4·40	4·37	4·37	4·38	4·37
Averages	4·22	4·34	4·36	4·37	4·43	4·32	4·26	4·32

The vertical column averages show the greatest variation to be 9·25 per cent., and indicate considerable carelessness in manufacture. The horizontal column averages, which reveal the reliability of the principle of the regulating apparatus, show that at 1-inch pressure the burners passed 5·5 per cent., and at 2·5 inches of pressure, 9·25 per cent. more gas than they were marked to pass. A study of the figures will show that the regulating apparatus is a good, although not a perfect one. The consumption of gas increases with the pressure from 1 inch to 2½ inches, and decreases from 2½ inches to 4 inches.

Experiment 5.—The burner used was a 4-feet public lamp regulator burner, with a regulating apparatus :—

	PRESSURES IN INCHES.							Averages.
	1	1·5	2	2·5	3	3·5	4	
A	4·18	4·35	4·35	4·33	4·28	4·28	4·32	4·30
B	4·35	4·48	4·56	4·52	4·68	4·63	4·52	4·53
C	4·23	4·30	4·32	4·32	4·33	4·37	4·33	4·31
D	4·13	4·18	4·31	4·30	4·20	4·27	4·22	4·23
E	4·22	4·30	4·37	4·35	4·40	4·37	4·12	4·30
F	4·41	4·47	4·57	4·65	4·63	4·63	4·80	4·59
Averages	4·25	4·35	4·41	4·41	4·42	4·42	4·38	4·38

The vertical column averages show the greatest variation to be 8 per cent., and indicate considerable carelessness in manufacture. The horizontal column averages show that, at 1-inch pressure, the burners passed 6·25 per cent., and at 3 inches of pressure 10·5 per cent. more gas than they were marked to pass. They also show that the regulating apparatus came somewhat slowly into action but that, for pressures of 1½ inches and upwards, it is as near perfect as can be expected; the variation from the average not exceeding 1 per cent. on either side.

Experiment 6.—The burner used was a 6-feet household regulator burner with a regulating apparatus :—

	PRESSURES IN INCHES.							Averages.
	1	1·5	2	2·5	3	3·5	4	
A	6·57	6·60	6·70	6·57	6·27	6·17	5·67	6·36
B	6·57	6·60	6·65	6·63	6·57	6·30	6·10	6·49
C	6·18	6·51	6·62	6·78	6·51	6·55	6·46	6·52
D	5·16	6·41	6·62	6·50	6·30	6·31	5·80	6·30
E	6·27	6·51	6·63	6·71	6·60	6·51	6·16	6·48
F	6·26	6·30	6·55	6·62	6·37	6·23	5·80	6·30
Averages	6·34	6·49	6·49	6·63	6·44	6·34	6·00	6·41

The vertical column averages show the greatest variation to be 3·4 per cent. The horizontal column averages show that at 1-inch pressure the burner passed 5·7 per cent., and at 2·5 inches of pressure 10·7 per cent. more gas than they are marked to do.

A number of other experiments were made, but they do not present new features, except the one which tested the burners to discover the pressures at which the regulators came into action. None of the regulators came fully into action at a pressure below 6·10ths of an inch, and most of them at 8·10ths. The net result of the experiments given is that regulator gas-burners can be made which will not vary in their consumption of gas, at pressures ranging from 1 inch to 4 inches, more than 1·15 per cent. fast and 2·3 per cent. slow of their average consumption. All that is necessary, therefore, is to get the regulator accurately set, and its limits of error are known. The Sale of Gas Act defines a meter as correct which does not register more than 2 per cent. fast or 3 per cent. slow. The tests given herein show that regulator gas-burners can be made as correct as gas-meters.

The question now arises: Do regulator gas-burners in use on public lamps, where exposed to all weathers, temperatures, and barometric pressures, give equal results to those found in the testing-room? The writer is honoured by Mr. Philip Monson, the Gas Superintendent for the parish of Kensington, placing at his disposal the results of the average meter system for eleven years. Each lamp has a regulator burner set to burn 4·5 cubic feet of gas per hour. The meters are read each month, and the records have been carefully collected. More than 4000 lamps are in use on the meter system. The following table shows the average consumption per lamp per hour for each of the eleven years :—

Year	Cubic Feet.	Year	Cubic Feet.
1877	4·55	1884	4·49
1878	4·57	1885	4·49
1879	4·50	1886	4·52
1880	4·43	1887	4·54
1881	4·46		
1882	4·50		11)49·53
1883	4·48		
		Average	4·503

These results are a convincing proof that regulator gas-burners may be relied upon in actual use. The writer has compiled the following table from Mr. Monson's records, showing the average consumption per lamp per hour for each month of the eleven years :—

Month	Cubic Feet.	Month	Cubic Feet.
January	4·38	September	4·53
February	4·51	October	4·49
March	4·45	November	4·50
April	4·53	December	4·39
May	4·49		
June	4·61		12)54·01
July	4·60		
August	4·53	Average	4·501

It will be noticed from this table that the lowest consumption occurs during those months when the hours of lighting are longest, and that this gives an advantage to the local authority if the average meter system is adopted. The following table, based on 4300 hours' lighting per year, shows the amount of this error :—

Month.	Hours of Lighting.	Cubic Feet per Hour.	Total Cubic Feet per Lamp.
January	484·03	4·38	2120·0514
February	397·75	4·51	1793·8525
March	375·68	4·45	1671·3310
April	303·90	4·53	1376·6670
May	260·41	4·49	1169·2409
June	224·52	4·61	1035·0372
July	246·30	4·60	1132·9800
August	294·01	4·53	1331·8653
September	341·90	4·53	1548·8070
October	414·67	4·49	1861·8683
November	454·95	4·50	2047·2750
December	501·98	4·39	2203·6922
Totals, &c.	4300·00	4·50	19,292·6678

If the consumption had been taken from the burners alone, it would have stood at $4300 \times 4.5 = 19,350$ cubic feet per lamp per year, as against 19,292.6678 cubic feet given by the meters, or an error in favour of the gas company of 57.3 cubic feet per lamp per year. In London the price of gas to the public lamps north of the Thames is 2s. 2d. per 1000 cubic feet; so that the saving to the local authority for gas by the average meter system, is 1½d. per lamp per year. Against this there is the cost of the average meter system. The following figures refer to a district containing 4000 lamps, with a meter to every 20 lamps.

Capital Expenditure.

200 meters fixed complete, at £7 10s. each £1500

Annual Expenses.

Interest, depreciation, and repairs on meters, 10 per cent. on £1500 £150
Man's time reading meters: 12 weeks per annum, at 25s. a week 15

This cost, divided over 4000 lamps, equals 9.9d. per lamp per annum, which is incurred to save 1.5d. per lamp per annum.

The figures given refer to a district where the minimum parliamentary limits of pressure are 10-10ths from sunset to midnight, and 6-10ths from midnight to sunrise. As a matter of fact, however, the actual pressures are in excess of these limits. From the continuous recording pressure-gauge in the testing-room at Chelsea, it is found that the pressure does not go below 1.2 inches at any part of the day; and that from one hour before sunset to half an hour after, the pressure rises to 3 inches and even more, and then gradually falls to 1.4 inches by midnight. Where pressures like these are given, the writer is of opinion that the average meter system is an unnecessary check and expense. It may be that in small districts the pressures fall below those stated as the parliamentary limits; and in such cases the regulator burners would not pass their full quantity. The remedy, however, is to make the gas company give a proper pressure, and so save the expense of the meters.

In the course of the subsequent discussion,

Mr. J. LEMON, M. Inst. C.E. (Southampton), said he thought they were all much indebted to Mr. Strachan for his valuable paper; but he must say that the conclusions the author drew were not all in accordance with his. If they could get a gas-regulator perfectly made, then it would do very well indeed; but his experience was that there was no such thing as a perfect regulator. A regulator was only intended as a check upon the consumption when there was great pressure. As regards meters, it was quite true that the percentage given as to the correctness was 2 per cent. one way and 3 per cent. the other. They must have a certain amount of margin. They could not expect that every person would have an absolutely correct meter; and therefore this small margin of 2 and 3 per cent. was allowed in testing meters, so as to provide against that little irregularity which must occur in every mechanical appliance. He took exception to the annual expenses—interest and depreciation—10 per cent. on £1500. He introduced the average meter system in his borough; and he could say that it never at any time cost anything like 10 per cent. for repairs of meters. He considered the 10 per cent. for repairs altogether an outside item. Then as regards the man's time, he used to employ one of the assistants in the office to go round with the man to check the meters; so that there was no extra cost to the borough in this respect. It should be done by the staff in the office; and therefore he thought the item—though it was only £15—ought to be struck out. It seemed rather absurd to spend 9.9d. per lamp to save 1½d.; but, in answer, he said that the gas-regulator was unreliable, and it was necessary to have a meter to get anything like a fair record of consumption. The gas-meter was the only reliable record; and the gas-regulator was not to be depended upon.

Mr. J. HALL, Assoc. M. Inst. C.E. (Torquay), considered that the regulator was as absolutely necessary as a check upon the meter as the meter was a check upon the workmen.

Mr. LEMON: What I say is that you must use the two.

Mr. HALL (continuing) said, as to cost, that the capital expenditure of £1500 appeared to him to be an excessive amount for the size of the meters that were used in street lamps. The depreciation—10 per cent.—seemed also to him to be more than was usual. In regard to reading the meters, he took them four times a year. He went round himself, and read the whole of them in an afternoon for 600 lamps. He did not think they could depend upon an ordinary workman for doing it.

Mr. T. FARRELL (Sherborne), remarked that, in his town, they used the average meter system. The meters were the property of the Board; and they were read once a quarter. It took about 1½ hours to read them. In regard to expense for repairs, the meters had not cost them anything under this head during the eight years they had been in use. The Gas Company were perfectly satisfied with their registration; and so they went on comfortably enough. With respect to the question of governors, he had one of the old night lamps which was situated at the bottom of a street 400 or 500 yards long, and another at the top of the street. One would think that the lamp at the top would consume more than the lower one; but it was quite the reverse—the latter consuming 10 or 15 per cent. more. This, he supposed, was accounted for by the governors not working properly.

Mr. BENNETT (Southampton) said he found that in his town the depreciation was something like 4 instead of 10 per cent.

Mr. EDEB EACHUS (Edmonton) inquired whether it was not worth while to incur expenditure for checking equal to 2 per cent.

on the annual expenditure. There were 4000 lamps at £2 a lamp. The expenditure to check the regulators was £165, or 2 per cent. on this amount; and he thought an engineer would regard this as being a small expenditure to check a large one.

Mr. NORRINGTON (Fulham) drew attention to the fact that different sized regulator burners were used in the experiments. When they dealt with 4-feet regulator burners they obtained truer results; but when dealing with 5-feet and 6-feet regulators they had irregularities.

Mr. GLEDHILL (Heckmondwike) gave it as his opinion that gas-regulators were not to be depended upon. He had far more trouble with the regulators than with the meters.

Mr. GODFREY (King's Norton) said that considerable difficulty arose from the joint partnership of the gas company and the local authority. He would suggest a plan by which this could be avoided—viz., the one adopted by Birmingham, where the local authority provided the meters and the gas undertaking maintained the regulators. If the latter found a regulator bad, they put a new one up. If both meter and regulator belonged to one body, there was sure to be dissatisfaction.

Mr. DE C. MEADE, Assoc. M. Inst. C.E. (Hornsey), said that the author had not given a description of the regulator used. Some did not last anything like so long as others. The old-fashioned one, with the leather diaphragm, lasted a fair average time in fine weather; but wet weather interfered with it. The new metal and steatite regulators lasted longer; but the accumulation of naphthalene from the gas affected the one, and did not affect the other—the steatite—to so great an extent. They had a very simple check in the portable photometer, if they suspected they were not getting the full illuminating power from the gas. They could easily test it; and he really found that they obtained more light than they paid for. This saved all the trouble and expense of the meters. The regulator system, as practised in many of the large districts in London, was a very satisfactory one.

Mr. WEAVER (Kensington) said Mr. Strachan was to be commended for the careful experiments he had made with regard to the lamps in Chelsea. He (Mr. Weaver) thought it would be somewhat premature to adopt Mr. Strachan's system of regulators to the lamps, in preference to the meter system. When they applied the average meter system in Kensington, in 1877, they had a good deal of difficulty to get the Gas Company to agree upon the position of the meters, and to get them down as low as possible in relation to the number of lamps. When the system came into force, he flattered himself that he had done a good thing for the parish; and the next annual report showed a considerable saving in the expenditure for gas as compared with preceding years. One of the great difficulties he saw in depending entirely upon regulators attached to the burners would be that of getting the number of hours of lighting in a large district. For instance, in the case of fogs coming on in winter, he was quite sure there would be some difficulty in keeping a proper record of the lighting. If the company were done out of only half an hour for some 4000 lamps, it meant a decimal of a penny for each lamp.

Mr. J. HEPWORTH, Assoc. M. Inst. C.E. (Carlisle), said that he had listened to Mr. Strachan's paper with very great pleasure; and for the most part he quite agreed with the conclusions he had arrived at. He thought the experiments pointed more than anything else to the fact that they could get good regulators if they chose to do so. He had under his care 1400 or 1500 lamps; and they had not felt it necessary to adopt the average meter system because the gas-works belonged to the Corporation, who also owned the lamps. He had made very careful experiments with regulators; and he thoroughly agreed that for the most part there was no necessity to adopt the average meter system. But where, as Mr. Strachan pointed out, they had a gas company supplying at irregular pressures, then the average meter system became advantageous. They might also have to light at irregular hours, and then the average meter system became valuable. If, however, the hours and the pressure were regular, then they might certainly depend upon having as good results from the use of regulators as by meters and regulators combined.

Mr. STRACHAN, replying upon the discussion, referred in the first place to the cost of the average meter system. He did not think anyone would quarrel with his estimate of £7 10s. for a meter fixed in the box. And if £7 10s. was a fair estimate, then the cost of 200 meters came to £1500. He was willing to allow that a gas-meter had 20 years of life, which he presumed no one would say was inadequate. Depreciation on that was 5 per cent.; and as they could not borrow money in London under 3½ per cent., that made 8½ per cent. They could not do repairs at less than 1½ per cent., and that was 10 per cent. on the £1500; and this he submitted was a fair and proper estimate. Mr. Lemon also said that they did not pay for the time of the assistant. It was no answer to the argument to say they had "in the house" the assistant to check the meters, and that therefore it did not cost anything. He contended that his estimate in this respect was also fair and proper. He was prepared to follow Mr. Lemon's opinion in various matters; but when he (Mr. Strachan) had had eleven years' experience pointing entirely in another direction, he hoped Mr. Lemon would pardon him for not accepting his opinion. At Kensington the average meter system had recorded good results, which were these: That for eleven years they had burned upon the average 4.503 cubic feet; and their regulator burners were set at 4.5 cubic feet. This was as near as one could come to in this world. If eleven years' experience showed that the regulator burners were as accurate as the meters, then of what use were the

meters? This was the point which had not been answered. As to Mr. Weaver's remarks, they had never used any other system than this in Chelsea; and as to how they managed in the case of fogs, he left it to the Gas Company to find out that the lamps had been lit up—(laughter)—and then he simply stated that they started so many hours sooner. He unhesitatingly said that they saved all the expense of the average meter system. The accident of his having 4, 5, and 6 cubic feet regulator burners was owing to the makers not having any others in stock.

Mr. JOSEPH C. INGHAM, of Bury, has been appointed Manager to the Ramsbottom Gas Company.

At the meeting of the Heywood Town Council last Thursday, the salary of the Gas Manager (Mr. H. Hawkins) was increased by £20 per annum.

AMONG the numerous amendments proposed to the Local Government Bill was one empowering the County Council to present to Parliament a scheme for London District Government, and schemes for taking over the powers of the Gas and Water Companies. Clauses embodying these proposals were placed upon the paper by Mr. J. F. B. Firth; and it was suggested that they should follow the 38th clause in the Bill. The terms of the proposal were as follows:—"The County Council of London shall, as soon as may be, submit to Parliament a Bill for the rearrangement of municipal government and administration within the area of the county of London;" and also one "for the purchase or regulation of the undertakings at present supplying respectively water and gas to any part of London, or any of them, or for the provision of a new supply of water, gas, or light to London or any part thereof." These clauses have not yet come before the House of Commons for discussion.

THE French journal *Science Pratique* remarks that the great modern extension of the use of nickel plating for objects of domestic ornament and utility, including gas and water fittings of all kinds, renders it interesting to know how these articles may be cleared from the film that gathers upon them in the course of usage and exposure to the atmosphere. There is an appearance of rust upon old nickelled ware which may be removed in the following manner:—The surface to be cleaned is first greased, and the grease allowed to remain for a day or two, when it must be removed by means of a rag dipped in ammonia. If any spots remain after this treatment, they may be very carefully wetted with a little dilute hydrochloric acid, which must be immediately wiped off. Afterwards the goods must be washed with water, and, when dry, polished with tripoli. In this way, unless the plating is actually worn off, an old nickel plated article may be made to look as good as new.

THE Select Committee on Private Bill Legislation have now agreed upon the terms of their report, and concluded their labours. Two draft reports were before the Committee. The first, submitted by Mr. Courtney, recommended that all Private Bills be considered by a Commission appointed for the purpose; and if approved by this body, should be laid on the table of the House for a certain period before becoming law. The second report, drafted by Mr. Stanhope, also adopted the principle of an outside Commission, but delayed the reference thereto until after the Bill should have been read a second time—in other words, substituting the Commission for the present Committee stage. In recommending the appointment of a Commission, the Committee have suggested that, while its head-quarters should be in London, it should have power to sit in different parts of the United Kingdom, and should be authorized to conduct inquiries by means of one of its members, with two assessors added. It was felt that Mr. Courtney's proposal would involve too radical a change to meet with the approval of members generally; and the second scheme was agreed to. The report, as will be seen by our "Parliamentary Intelligence," was presented to both Houses last Thursday.

MESSRS. J. STOTT AND CO., of London and Oldham, manufacturers of consumers' gas governors, have just opened a new Manchester branch, in the most central portion of the city; their previous accommodation having been found insufficient. The firm, which was scarcely known a few years ago, has sprung into considerable prominence through the reputation gained by their now well-known automatic governors, and at present have branches in nearly all parts of the world. The principal works—where a large number of people are engaged—are at Oldham; and there are also works in Allegheny City (U.S.A.), where they make governors chiefly for controlling natural gas. This is often delivered to consumers at the enormous pressure of 800 inches; but by the action of the Stott governor, it is easily brought down to half an inch. The chief advantages claimed for the governor are exceeding delicacy, accuracy of governing power, and absolute reliability and durability. The construction is such that the action is entirely direct, or it may be said to work on the dead-weight principle. There are no levers or other points of friction, which is an important matter in a self-acting machine actuated by so light a motive power. The 8-inch governor is so carefully adjusted that it will control a single light just as well as the smallest governor made. The materials used in construction are of an imperishable nature, so that the chances of the governor getting out of order are reduced to a minimum; and the makers guarantee it for seven years. The firm have received upwards of 40 highest awards for their governor in competitions; including prizes gained at the Adelaide, Antwerp, and London (Inventions and American) Exhibitions, at the latter of which the American house competed,

HALF-DEPTH REGENERATIVE FURNACES.

At the Eleventh Annual Meeting of the Western Gas Association, held at Chicago from the 9th to the 11th of May (a general review of the proceedings at which, taken from the "Official Report" in the *American Gaslight Journal*, is now appearing in our columns), one of the papers read was on the above-named subject; the author being Mr. F. Bierce, Engineer and General Manager of the Memphis (Tenn.) Gas Company. The following is an abstract of the communication:—

The author explained, at the outset, that the paper was intended rather as a practical recital of conclusions obviously deduced, than an attempt to digest the whole science of furnaces. He then asked, What constitutes a full-depth regenerative furnace? To this question he was unable to give an answer, as he confessed he did not know how to characterize the difference between a full-depth and a half-depth furnace. But on the supposition that the former was a furnace measuring anything from 5 or 6 feet to 12 or 15 feet, according to fancy, the latter should be anything from 2½ to 7 or 8 feet. To carry out the idea of regeneration profitably in practice, the simpler and more inexpensive the device the better. The author built ten benches of sizes, 14 in. by 26 in. and 9 ft. long. He was so situated that he could not excavate low enough for deep furnaces, on account of high water interference; and he did not think fit to elevate, as he had stacks of arches that were good, and he did not want to abandon them. He felt, however, that he could, with a shallow regenerative furnace, on a four hours' run, produce sufficient heat to carbonize as much coal of the kind he used (Pittsburgh) as the retorts would carry without suffocation, to get from the coal a maximum quantity of gas with a minimum of fuel and labour in keeping with his ambition at the time. He proceeded as follows.

It is, I believe, asserted, if not conceded, that a good quality of carbonic oxide is not produced by the passage of air through a bed of fuel less than 2 feet deep, when gas coke is used, from the accustomed draughts in the flues of any ordinary coal-gas bench. It is my observation that good carbonic oxide is produced only from at least 2 ft. 6 in. depth of gas coke, when draughts are not impeded, and a somewhat lively draught is required, unless the furnace be extraordinarily deep. Therefore, I should say, as the result of my observation on this point, make the fuel chamber at least 3 ft. 6 in. deep, for the reason that it requires replenishing once in four hours only (and I believe that it is one aim with all regenerative furnaces to replenish as seldom as possible). A furnace of this depth, and proportioned in width, to be filled full when replenishing, with not over 33 per cent. of the coke drawn from the retorts above, will, in practical use, for good results consume down a foot or more to a point where there is no longer a good quality of carbonic oxide produced in the combustion below; and this is readily determinable from the colour of the product of combustion as it emerges from the top of the fire, also the rapidity of combustion below that point, and its receding distance from the retorts.

I believe no one will deny the claim that a large fire is hotter than a small one of the same degree of incandescence. Now, the combination of these two facts—a large fire and a thorough carbonization of the oxygen—is the fundamental basis of furnace heats, as I view the subject; and starting out from this point of consideration, what is sought is the constructive device for regulating this combination in the most economic consumption of fuel. Following along this line of illustration, if a deep furnace is hotter than a shallow one, the reason is clear to me that the oxygen, the agent of combustion, is carbonized in a stronger degree; which means that if you make one deep enough and put steam enough under the grate-bars, so as to press the combustion area up as near the retorts as possible, at the same time giving it a strong draught, one can quickly destroy the retorts above. On the other hand, if properly constructed on the regenerative principle, the oxide can be converted to acid to any desired extent, and at the same time the rapidity of combustion checked by dampers on the primary air supply—both compensating each other in proportion to the amount of waste products of combustion issuing from the exit chimneys in comparison with the degree of heat attained upon the retort. For example, if there is not enough heat on the retorts, and there are too many waste products, give more secondary or less primary air. Again, if there is not enough heat on the retorts, no waste products, and yet a rapid combustion, it shows that the product of combustion is spent—i.e., the chemical union takes place (at which point is the centre of heat) too low down in the furnace. So just give the furnace some more steam from below, so as to drive or press forward or upward the point of that chemical conversion, so that it takes place where you want it—among the retorts above, instead of in the furnace below. This latter, however, I have found to be fruitful of luxuriant growth of clinker—a chemical combination not much desired—and has its disadvantages.

In this connection it is also my experience, as well as observation, that sufficiently good results are accomplished with a furnace such as I have for my subject, with diligent use in the hands of competent persons; for as profitable distillation of coal can be effected in retort-benches of sixes as I have seen from very deep ones. It may be said, I think, speaking in a general way, that just so much gas of a given quality can be taken from a certain quantity of coal and no more, and that a given sized retort can be charged with so much coal for perfect carbonization and no more, and that a retort will stand just as much heat, according to how much coal is being distilled in it, and no more, without its too

rapid destruction; the object being to accomplish these things by as short a process as possible. Here, then, enters the great agent of complication in all scientific investigations—that of cost and compensation.

A shallow regenerative furnace can be built much cheaper than a deep one; and the life of the two, I imagine, should be about the same. My furnaces cost me between \$500 and \$600 each, including retorts and mouthpieces, and the arch filled complete and connected up; and I have seen deep ones that were said to have cost several thousand dollars each. It looked a little extravagant; however, the difference is great in cost, and little, if any, in compensation. This is my conclusion after comparing results carefully.

With the same fidelity to a deep furnace that I have to a shallow one, I must say that I believe a deep furnace can be manipulated much more easily than a shallow one, considering the character of the common labour in a gas-works as a rule, and the measure of intelligence found in furnace stokers; that the successful or profitable use of a deep regenerative furnace can be more readily depended upon, because it requires less attention and the exercise of less judgment—its advantages being more easily comprehensible, as it appears to me.

It would perhaps be interesting to have shown briefly some comparison of results between the old primitive design of furnaces and the half-depth or shallow regeneratives, as I am operating some of each alongside of each other, only in separate stacks, so that heats are not contiguous; and I get as good carbonization of 50 per cent. more coal from a half-depth regenerative, at an expense of not more than 30 per cent. of the coke, as I do from the old design with a consumption of nearly, if not quite, 58 per cent. of the coke, besides averaging six retorts per man instead of four retorts per man with the old design, without imposing any more trouble on the men beyond the work being hotter.

Another thing of by no means secondary importance in connection with half-depth or shallow regenerative furnaces is the method of introducing the hot coke immediately from the retorts into them—an indispensable adjunct. I had not seen a very systematic arrangement for feeding them; and I spent some thought on this feature. My hot coke is drawn from the two top retorts at the same time through a funnel into the furnace below—this funnel being a very unique implement for the purpose, original in design. In resemblance it impresses one with the idea of the spread eagle. It bears the cognomen, among the negro labourers using it, of the native Southern bird, the buzzard. When we are not using it I hoist it out of the way overhead by means of a $\frac{1}{4}$ -inch wire tiller cord over a couple of 3-inch pulley blocks and a small windlass, and lower it quickly into position for use. It is at once useful, handy, comparatively cheap, entirely simple, and its utility indispensable in connection with furnaces constructed as mine are. I should not refer to this hot coke funnel had I not come to regard it as a part of the system of shallow regenerative furnaces, in utilizing the coke in its incandescent condition.

Replying to questions put in the course of the discussion on the paper, Mr. Bierce said that if he turned on more steam below the grate, it improved the heat in the retort-setting, but at the same time increased the clinker. The latter, however, was softer in character. He clinkered once every 24 hours, and his steam supply was carried in a $\frac{3}{4}$ -inch pipe under a pressure of 60 lbs. Coke breeze was used to raise the steam, and the cost was merely nominal. As shown in his paper, the half-depth furnace could be adapted to the old-pattern arches by excavating a little deeper. The primary air supply was not heated; and he admitted plenty of it—keeping the ashpit door open. He charged from 250 to 300 lbs. of coal into each retort every four hours, and was not troubled with stopped ascension pipes. Mr. Dunbar had worked a bed of three retorts on a similar plan to the one he had laid before the members, with equally good results; but he found that the more steam he admitted the less was the clinker. He supplied the steam from a $\frac{3}{4}$ -inch pipe having holes $\frac{1}{8}$ -inch diameter and 8 inches apart. Mr. Grimmer had been running regenerative benches since 1882, and found they did not want much steam, also that the primary air supply must be well under control. Too much steam reduced the heats; and an opening $\frac{3}{4}$ in. by $2\frac{1}{2}$ in. was quite sufficient for the primary air when the bench was in good order.

THE MANAGEMENT OF THE BROMLEY (KENT) GAS CONSUMERS' COMPANY.—In the JOURNAL for the 12th ult., we intimated that Mr. John S. Dougall was about to resign his position as Engineer and Manager of the Bromley (Kent) Gas-Works. We have now been officially informed that Mr. Dougall's engagement with the Company has terminated.

A LIGHT FOR NIGHT WORK.—Much of the work in connection with the Manchester Ship Canal is being done at night. For this purpose an artificial light is employed, produced from the combustion of oil-gas made from a cheap form of refined tar or creosote. Messrs. A. C. Wells and Co., of Ardwick, have devised and patented an ingenious apparatus for the production of light from this gas; and a light equal to between 2000 and 3000 candle power, of a pure white and steady quality, is obtained. The cost, it is stated, does not exceed 3d. per hour; and petroleum can also be burnt, if preferred, though at a somewhat greater cost. The light being self-contained, there is no need for the employment of steam or air compressors; and being perfectly portable, it can be easily moved as required.

Register of Patents.

DESULPHURIZATION OF GASEOUS PRODUCTS.—Hood, J. J., of Shepherd's Bush Road, W., and Salamon, A. G., of Fenchurch Avenue, E.C. No. 10,127; July 19, 1887. [6d.]

This invention relates to the use of "Weldon mud"—artificially prepared hydrated oxides of manganese—in the desulphurization of gaseous products, so as to fix and recover the sulphur in a merchantable form. The patentees read a paper on the subject before the Society of Chemical Industry last January, as reported in the JOURNAL (Vol. LI., p. 64).

The specification of the invention (which is not illustrated) states that the patentees propose to employ the "mud" either by forcing the gas through the manganese mud held in suspension in water, acidulated or not acidulated, or else the mud is washed practically free from calcium chloride, drained (and if not sufficiently porous, mixed with plaster of Paris or other suitable material), and dried, and placed in layers in a convenient apparatus; the gas being passed over and through it. In desulphurizing gases, such as coal gas, containing sulphide of carbon in addition to sulphuretted hydrogen, besides using Weldon mud to fix the latter, some of the manganese sulphide is employed to absorb or fix the bisulphide, just as lime sulphide is used for a similar purpose. After the manganese mud has been fully charged with sulphur, it is exposed to atmospheric oxidation; and thus rendered again efficient for desulphurization. This revivification may be repeated five or more times, until the material becomes highly charged with sulphur; and it is then treated as follows:—The manganese residues obtained by the desulphurizing process are dissolved in acid; and the free sulphur that deposits is separated—there being little or no sulphuretted hydrogen evolved during the dissolving, if the material has been previously exposed to the atmosphere for some days. The manganese solution is again precipitated with lime; air is blown through to effect oxidation; and the mud, after washing and drying, is again ready for use.

INCANDESCENT GAS-BURNERS.—Imray, O.; communicated from Auer von Welsbach, C., of Vienna. No. 11,195; Aug. 16, 1887. [6d.]

This invention relates to the now well-known Welsbach incandescent gas-burner, as described in patents No. 15,286 of 1885, and No. 3592 of 1886.

It has been found, says the patentee, that by using certain salts of other metals than those previously named, incandescence bodies are obtained which, although not of such advantageous application, may be employed with good effect for strengthening the mantles on account of their property of becoming more or less vitrified by the heating process. These salts are: 1. The niobates of the rarer earths, such as the niobates of thorium, beryllium oxide, cerium oxide; also niobates of zirconium, magnesia, calcium oxide, and alumina. 2. The tantalates of these earths, mixed with each other according to their stoichiometrical proportion. 3. The silicates of the earths, either alone or mixed together in stoichiometrical proportions. 4. The titanates of the earths and mixtures thereof. 5. The phosphates of the earths, and mixtures thereof. 6. Also mixtures of the several salts enumerated under the preceding heads may be used. In using these various salts, the mantles after impregnation by the salts of the rarer earths as described in the previous patents, are impregnated or coated a second time with a solution of the above-named salts or mixtures thereof, by preference at the upper end of the mantle only, where it is supported by the platinum wire. After this the mantle is subjected to the action of a Bunsen flame, as described in the prior patents, for the purpose of burning away the fibrous material and converting the salts into oxides. In order to facilitate the burning away of the fibre, the salt-solution with which the mantle is to be impregnated, may with advantage have mixed therewith some ammonium nitrate. For rendering the prepared mantles better able to stand transport or rough usage, they may with advantage be dipped into a very weak solution of caoutchouc or collodion, which is allowed to drain off and solidify; and this is afterwards burnt off by subjecting the mantle to the heat of a flame in the ordinary way.

GAS-BURNERS.—Pintsch, J., of Berlin. No. 11,298; Aug. 18, 1887. [8d.]

This invention relates to a Bunsen burner "for gas incandescent light illumination, in which a conoidal body is arranged quite or partly in or above the burner orifice for the purpose of obviating explosions in the flame above the burner orifice, and consequently the noise of the flame."

This conoidal body is fixed upon a star-shaped disc set upon the enlarged burner tube orifice A, fig. 3, in such a manner that the mixture of gas and air passes from the burner tube uniformly around the body upwards. Moreover, in order to secure the proper position of the burner tube B, fig. 4, relatively to the burner, upon the tube or enlarged orifice is placed a cylindrical, tapering, or conoidal capsule D, at a uniform distance from the conoidal body, and over the upper end of which the lower end of the tubular incandescent body D (suspended from a rod or frame) is drawn. By reason of the conical body, the green core of the flame will assume an annular shape; and the hottest zone of the flame is displaced

further towards the periphery of the same. Now, says the patentee, as the tubular incandescent body must (owing to the capsule) always remain central relatively to this hottest zone of the flame, the flame will always render the body G incandescent with uniform intensity, and the incandescent body will not be able to change its form. The capsule D and the conical body are both made of refractory material, such as steatite. The capsule D receives a small flange above, extending inwards in such a manner that the flame formed of the mixture of gas and air rising from the annular space between the conical body and the capsule is sufficiently enclosed to remain, especially at this point, at the proper distance from the incandescent body.

GAS-BURNERS.—Haddan, H. J.; communicated from W. M. Jackson, of Washington, U.S.A. No. 5331; April 10, 1888. [8d.]

Fig. 1 shows one form of this burner, for use with an ordinary pillar connection; and fig. 2, a burner with a different regulating device combined with it.

In the former case, A represents the shell of an ordinary house burner, with its tip attached. Into this shell is inserted a gas-regulator B, which consists essentially of a short cylindrical cup A¹ made to fit and slide loosely within a receiving cylinder A²; being provided with a lateral projecting flange which enters a rim turned upon a flat disc I that forms a bottom plate, and which is turned over upon the flange on the cylinder A², and thus holds the parts together. A central orifice is made in the bottom plate; and a similar perforation is made in the top of the cylinder A¹. Small orifices are made in the side wall of the outer cylinder A², which the wall of the inner cylinder A¹ will measurably close when the pressure of gas that enters the inner chamber causes it to rise. The opening in the chamber A¹ is made of sufficient size to pass the predetermined quantity of gas to be consumed under the lowest pressure adapted as a standard of regulation—say 4.10ths of an inch. Under such conditions the hole would be about $\frac{1}{16}$ inch in diameter for 5 feet of gas per hour of about .600 specific gravity. The perforations in the cylinder A² have a delivering capacity greater than the hole in the cylindrical chamber A¹; and their location is such that the top surface of the chamber will line with the lower edges of these perforations when it is made to rest upon the bottom plate.

In fig. 2 a modified form of burner shell is shown; consisting of a base E threaded interiorly to fit a fixture, and flanged at its upper end to form an upturned lip adapted to overlap the flange of the upper section D of the burner shell, and secure it in close connection by wedging it down thereon. The remaining features of the regulator are similar to that shown in fig. 1.

GAS-LANTERNS.—Drew, H., of Clapham, Surrey. No. 6545; May 2, 1888. [6d.]

This invention relates to the construction and arrangement of lanterns for gas and other burners whereby they are rendered more portable, take up less space when packed for transport or storage, and certain portions of them are said to be more efficient, more durable, and less costly than corresponding parts of lanterns in ordinary use.

GAS-HEATED BATHS.—Wright, J. F., and G. E., of Birmingham. No. 6659; May 4, 1888. [6d.]

This invention consists of the combination, with a gas-heated bath of coils of tube through which the water flows to the bath, placed in a heated chamber underneath the bath, and in such a position as to be heated by the flames by which the bottom of the bath itself is heated.

GAS-STOVES.—Saul, D. H., of Shoreditch, London. No. 7236; May 15, 1888. [6d.]

This gas boiling and heating stove consists of two vessels of cast iron fitting loosely one within the other; the space between the two forming the gas-burner. The outer vessel is of cylindrical or other form; the inner is of cup-like form surmounted by rests, for the purpose of placing thereon any vessel to be heated.

APPLICATIONS FOR LETTERS PATENT.

9893.—JONES, J., "Improvements in vertical or inclined retorts for distilling shale, coal, and other analogous substances." July 7.

9917.—HAYMAN, J. M., "Improved attachment for gas-burners." A communication from—Shilton. July 7.

9947.—RAISON, H., "Improvements in water motors or meters, combined or separate." July 9.

10,014.—NICHOLLS, R., "Improvements in regulators applicable to gas, water, air, and steam." July 10.

10,043.—KITSON, A., "Improvements in carburetting gas-lamps." July 10.

10,165.—PURNELL, J. J., "An improved gas motor engine." July 12.

PATENTS WHICH HAVE BECOME VOID.

[AFTER THE FOURTH YEAR.]

5794.—BOULT, A. J., (Jones), "Generating gas from hydrocarbons."

5797.—LINFORD, C. T., and another, "Gas-engines."

5820.—COX, W. N., "Rotary water-motor."

5835.—HARRISON, G. K., "Gas-retorts."

5874.—HILLS, F. C., "Gas liquor for the purification of coal gas."

5932.—IRVINE, R., "Distillation of coal."

Correspondence.

THE PHOTOMETER QUESTION AT THE GAS INSTITUTE MEETING.

SIR,—The Gas-Works Clauses Act, 1871, Schedule A, Part I.—"Regulations in Respect of Testing Apparatus"—prescribes that the apparatus for testing the illuminating power of the gas shall consist of the improved form of Bunsen's photometer, known as Letheby's open 60-inch photometer, or Evans enclosed 100-inch photometer. The Act does not give any dimensions or other description of the instrument; so that, according to the convenience of the interested parties and to the circumstances of the case, they may carry out the verification of the illuminating power of gas either in a completely dark room or in any ordinary office or room not specially devoted to this sole purpose. Accordingly, for many years past both gas companies and corporations, or local authorities working under the provisions of this Act, have used their discretion, and employed either the Evans or the Letheby photometer, as suited their convenience; and no question has, I believe, hitherto arisen as to any difference in the results obtained with either of these instruments. My own experiments have always shown them to give like results with my 10-candle standard. In fact, both instruments have been adopted by other countries as Government standard instruments, although in this country the Standards Department of the Board of Trade do not possess a standard photometer. They have, however, stamped as a standard instrument an Evans photometer for the Government of New South Wales; the sectional area of this instrument being the same as that of the later forms adopted by the London Gas Referees. They have also stamped a Letheby photometer fitted in a chamber, forming part of the instrument, of certain fixed dimensions, ventilated in a certain manner, for the Government of the Dominion of Canada, who have adopted it as the standard photometer. Both forms of these photometers, slightly modified according to the views of the Gas Referees, are used daily in the verification of the illuminating power of the gas supplied to London, under the most stringent code of regulations known to the world. Three tests only, made during any part of the 24 hours of the day, at the option of the examiner, are averaged, and this average is taken as the illuminating power for the day. Penalties are recoverable for a very slight deficiency.

In Paris the average of a week is taken; and penalties are only recoverable on the average of at least three months. The instrument mentioned by Mr. Dibdin, made according to his instructions, and called by him, in the tables given in his paper on "Photometers," the "open bar" or "portable" photometer, has never received the sanction of the Standards Department; but on more than one occasion, they have found that they could not stamp such an instrument as a legal measure for the verification of the illuminating power, unless it could be enclosed in a chamber of certain dimensions, &c., forming part of the instrument. Therefore I submit that the wholesale condemnation of Evans photometers, founded on comparisons made with that and his open bar in certain rooms, of which no particulars as to dimensions, ventilation, &c., are given, is not what Mr. Dibdin meant to be understood from his paper. I take it that he condemns "one of these converted old-pattern Evans photometers," because the readings made during a series of experiments, by six most experienced photometrists, were surprising.

I readily admit that I should be very much surprised if a 3-inch flame from a standard London Argand, consuming 5 cubic feet of gas per hour, showed a reading equal to 22 candles when tested against a non-variable standard; but I should not be surprised if I saw such a reading, under certain circumstances, after studying the table of results which Mr. Dibdin tells us he obtained when he compared 5 cubic feet of 16-candle gas against different parliamentary standard candles. (See his paper on "Standards of Light," published in the *Journal of the Society of Chemical Industry*, May 31 last.) I fancy if I expressed any surprise, it would be somewhat of that character which you might, perhaps, see depicted on the face of the Warden of the Standards, if he were told that a gentleman with an india-rubber rule had discovered that the Imperial standard yard was several inches too short. I do not say that the particular Evans photometer called the "old converted one" was quite so rigid an example of all that is correct as the Imperial standard yard; but I think that Mr. Dibdin's rule by which he measured it was more than a trifle elastic.

Looking at the third table, which treats of the Evans photometers No. 1 and No. 2, it is noticeable that they give, on the first day, readings nearly in accordance with Mr. Dibdin's "open bar;" the pair of readings being 16 candles by the Evans, and 16.3 candles by the open bar—the latter being the higher. On the second day the pair of readings are only 0.1 candle divergent—viz., 16.5 candles by the Evans, and 16.4 candles by the open bar. In another pair of readings on the same day, both instruments agree perfectly. On the third day the pairs of readings agree again, practically; the difference being that the Evans photometer read 0.1 candle lower than the open bar. On the fourth day there was a pair of readings in which the "open bar" was 0.1 candle lower than the Evans. And so on every day I find pairs of readings sometimes agreeing completely, and sometimes with very slight divergencies one way or the other, until the ninth day. Then comes a change. Photometer No. 3 (which I solemnly suspect is the "old converted one") appears on the list. Most surprising readings are the order of the ninth and tenth days; and these sensational operations, quietly tacked on to the average results of Nos. 1 and 2, go to prove the truth of the proverb that "evil communications corrupt good manners." "From these results," says Mr. Dibdin, "it is seen that the average by the Evans was 0.9 candle over that indicated by the open bar." But leaving out the suspected "old converted one," the difference is only half a candle between the two instruments; the Evans photometer reading the highest. It remains to be proved which of the two photometers is correct.

It is true that some may think that, in the eyes of a municipal officer, a type of photometer which shows half a candle in favour of the gas company should be a bad one. But Mr. Dibdin has earned for himself

the reputation of strict fairness in the discharge of his onerous duties; and no one will believe that any objection he makes against the Evans photometer is in any way influenced by this circumstance. I therefore venture to ask him why, seeing that during eight days concordant results were obtained from the Evans and open-bar photometers, like results should not always be obtained—all circumstances being equal. So long as there are gas examiners with different kinds of sight, and so long as it is convenient to use photometers in open rooms as well as in dark chambers, there must continue to be two kinds of these instruments. In hot climates, the Evans type of photometer is the only one which the gas company or the municipality will use. But both kinds will give equally true results if attention is paid to the ventilation of the room as well as of the instrument itself.

Mr. William King, of Liverpool, uses in the Gas Company's office a photometer which was originally designed by his father, Mr. Alfred King. This is really an open-bar photometer; there being no screens of any kind. It is used in the centre of a large high room with blackened walls. This is the prototype of all the photometers used at present, I believe, in gas testing in this country and in most parts of the world. The name "Bunsen photometer" has always appeared to me to be wrong. It ought, I consider, to be called "King's photometer with a Bunsen disc." The Corporation of Liverpool verify the gas by the aid of an Evans photometer; but I have never understood that there has been any noticeable difference in the average throughout the year between the results obtained by the Company and the Municipality. How the King open-bar photometer would work under the stringent regulations of the London Gas Referees has never yet been tried; but none of the London testing stations are anything like the room in which Mr. King's photometer is used.

From time to time the Metropolitan Gas Referees have introduced improvements in the photometers, testing-rooms, and apparatus—all tending towards greater accuracy and precision; but, as may be seen from the complaint of Mr. George Livesey at The Gas Institute meeting, any alteration must be made with great care, because a very small error, if made, involves great pecuniary consequences. The Gas Referees, as an impartial tribunal, have to decide whether Mr. Livesey's contention is or is not well founded, and whether the Evans or the "Imperial" standard photometer is an accurate instrument. This latter has never been sanctioned by the Standards Department of the Board of Trade, although it is possible the Warden might stamp it. The "Imperial" standard photometer is an attempt to meet the views of all the interested parties, and is the result of suggestions from the Gas Referees, the Gas Companies, and the Metropolitan Board of Works, put together by myself. It is a modification of the Evans photometer, first suggested by the late Mr. T. W. Keates, Chemist to the Metropolitan Board, and the predecessor of Mr. Dibdin.

There are so many points in Mr. Dibdin's valuable paper which are most interesting for discussion, that I am sure every one who reads it will join with me in regretting that it did not receive the amount of attention it deserved at The Gas Institute meeting. If my criticism of it, under one head only, helps to awaken that attention which the great importance of the question raised in the communication merits, I shall have done some service to all who are interested in photometry, and Mr. Dibdin's careful and laborious work will not have been undertaken in vain.

Westminster, S.W., July 7, 1888.

WILLIAM SUGG.

SIR.—I shall be glad if you will allow me to give my testimony on behalf of the Evans photometer. I have had upwards of 20 years' daily experience with it; and I am bound to say it does not deserve the censure passed upon it at The Gas Institute meeting. It is said by some that the ventilation is so bad that the air inside becomes so vitiated with carbonic acid as to affect the burning of the candles; and therefore the readings gradually rise. Why the candles only, and not the gas in the test-burner, should be influenced in this way, is not explained. The fact is that, in the old as well as in the improved form, the gas-burner creates such a current of air in the box, that if a little smoke is put in near the candles, and the doors are closed, it will be found to travel rapidly towards the burner; leaving the air clear in the candle end of the box.

Every winter, especially in foggy weather, the results obtained at the City testing station in Jewry Street, where I officiate, are lower than the Gas Company expect; and I have repeatedly taken off the top and the bottom of the photometer, and left the doors open, without apparently affecting the results in the least. On the other hand, I believe that the results have, at times, been considered too high (not by the Gas Company), and separate testings on an open photometer have been made for some days in a house near by Mr. Heisch; but, as I have heard nothing as to the results, I presume they confirmed the official testings. If doubtful results were due to some defect in the construction of the apparatus, the effect would always be the same; whereas I have in several instances known the same photometer to be blamed for giving both high and low results.

I do not think the suggestion of my friend Mr. Foster accounts for the rise in the readings in tests taken with the Evans photometer. In my opinion, it is due to the rate of consumption of sperm by the candles, which gradually becomes less towards the end of the ten minutes. This is caused through having to counterpoise the candles with the door open, when they are exposed to the draughts caused by the moving and even the breathing of the operator in front of them, the closing of the door, and the vibration consequent upon shifting the candles on commencing the observations. From these combined causes the consumption of sperm is greatest at the commencement, and least at the finish of a test; and hence the rise in the readings.

With the Letheby photometer, the conditions under which the candles burn are the same throughout the test; therefore the readings are more uniform. I am glad to see, by the discussion on Mr. Dibdin's paper, that there are many who think that candles properly used, are not so bad as they have been represented to be. As long ago as 1876 I called attention in the JOURNAL (see Vol. XXVII.) to a few of their weak points, showing that it was necessary, in order to ensure accuracy, to have the bend of the wicks at right angles with the photometer-bar; and I should like to say a little more about them now, but I fear I have taken up too

much of your space already. I will, however, with your permission, return to the matter at some future time.

Poplar, E., July 7, 1888.

W. C. YOUNG, F.I.C., F.C.S., &c.

THE PAY AND POSITION OF GAS MANAGERS.

SIR,—With many of your recent remarks on the question of gas engineers and their pay, and the relative position of the chief officials in corporations and companies, I very cordially agree. Events have occurred, and are still occurring, in the gas world which give point and emphasis to your strictures. The mild sneer at "clerical heads," in which you indulge, will, no doubt, be thoroughly enjoyed by the gentlemen to whom you refer; and they possibly, on their part, will flatter themselves that even you, Mr. Editor, do not know everything.

May I suggest that you do great injustice to certain towns you mention? The fact is that in these towns, in addition to the "clerical head," instead of there being only one engineer and manager, there are actually several, each of whom is responsible for the progress, efficiency, and satisfactory maintenance and carrying on of the work at his particular station. The system is found to promote healthy competition and friendly rivalry, and the working results afford to the Gas Committee and their "clerical head" the means of useful comparison. In the absence of petty jealousies, and with a cordial and good understanding amongst the chiefs, this system will work well. There will certainly be no need for any dark forebodings, even if it be necessary to call in an "experienced" engineer in reference to some unusually important work. These cases, however, are so exceptional, that it will scarcely be wise or economical to keep such an engineer on the spot, and pay him a large salary to attend to them when they arise. I suppose, too, that all engineers do not make good "clerical heads;" at any rate, I know some who figure very badly in the capacity of secretary or accountant. The duties of engineers, managers, secretaries, &c., are so different the one from the other, that no one man can possess in himself the best capacity for each and all of the positions. "Let the shoemaker stick to his last;" and, with easy and clearly defined duties, there will be no difficulty or irritating friction.

Certainly the tendency to cut down or not to pay proper salaries to efficient and trustworthy men of either class is a mean and mistaken policy. Good and upright men of ability are worth good salaries. A few hundred pounds, more or less, in salaries is a small matter compared to the loss or gain which may result from the operations of either engineers or secretaries, or the blunders of committees.

July 11, 1888.

RETORT.

MECHANICAL V. HAND STOKING AT THE MANCHESTER CORPORATION GAS-WORKS.

SIR,—In reply to Mr. Alderman King's letter, in your issue of the 10th inst., I did not intend to suggest that any outlay for new retorts, or setting them, was included in the accounts. I referred only to the foremen and retort setters and labourers named in my letter, whose duties are to clear out the flues, and scurf and repair the retorts while in action. Mr. King has certainly been misinformed, or he would not have stated that any men, more than those mentioned in my letter, were employed to open or auger the pipes—these duties being discharged by the stokers who open the lids, and whose wages were included in the cost I gave. But inasmuch as stopped pipes were practically unknown in the retort-houses where my machinery is in operation, this work was of a light character, although four and five hour charges are worked, and rather high heats employed. The charges for supervision, scurfing of retorts, &c., will vary and increase as the age of the retorts increases.

It is absolutely necessary, in making a comparison between any two systems of carbonizing, to define accurately what charges are included in the carbonizing account; for there is, in practice, great variety in the items that are comprised under the head of "carbonizing wages." For instance, in one case the wages for unloading and wheeling coal, wheeling and stacking coke, and even the exhauster men, will be included; while in another case the unloading of coal and delivering it into the retort-house will be booked to the coal account. The whole of the labour for handling the coke after it is out of the retort will be charged to the coke account, and the exhauster men will be charged separately, or to some other account. Therefore, I am inclined to think that engineers will look upon my figures as eminently practical, and the reverse of hypothetical—or, as Mr. King puts it, "theoretic."

What I point out in detail I still maintain. The cost of wages, from actual practice, by my manual machinery is 1s. 7-5d., and by the compressed air machinery, 1s. 2-82d. per ton; including, in both cases, coal wheeling, breaking and elevating it, machine men, coke wheeling—in fact, all charges from the taking of the coal from the stores to the tipping of the coke in the yard. The cost of the same work done by hand in Manchester is 2s. 6d. per ton.

It is not in Manchester alone that these statements can be confirmed, but in many other works where my machinery is in operation. The largest and most accurate trial, as to the cost of stoking by my machinery, and the amount of the saving obtained, was carried out by the Manchester Gas Committee themselves at their Rochdale Road works, before my appointment as Engineer of the department; and the results of the trial were published in the JOURNAL on March 23, 1880. For the purposes of the trial, No. 1 retort-house was completely isolated from the other parts of the works, and all the coal was carefully weighed, and the quantity and illuminating power of the gas taken. The quantity and cost, taken in each case on the same basis, were as follows:—

No. 1 Retort-House (West's Manual Machinery).
Gas made during five days 10,788,200 cub. ft.
Cost per 1000 cubic feet 1-68d.

The other Retort-Houses.
Gas made per house during five days 9,105,716 cub. ft.
Cost per 1000 cubic feet 3-01d.

Confirmatory evidence as to my accuracy can be found, by anyone who will analyze them, in the annual published accounts of the Gas Committee. I gather from the last annual statement (also from Field's "Analysis"), that the total quantity of coal and cannel carbonized at the various works in Manchester was 292,335 tons; the value of this quantity of coal being £178,301 6s. 8d., or an average of 12s. 2-38d. per

ton. The total wages paid for carbonizing was £32,636 1s. 4d., or an average of 2s. 2½d. per ton. By comparing the detailed charges, compiled in the same way, for each of the two largest works in Manchester, we can get at the cost for carbonizing at each works separately. The figures are as follows:—

Rochdale Road Works.

Amount paid for coal and cannel	£94,683 14 5
Tons of coal, at 12s. 2½d. per ton, to equal this money	155,239 tons
Carbonizing wages, including stokers, supervision and scurffing, &c.	£14,740 16 0
Carbonizing wages (as above) per ton	0 1 10⁄789

Gaythorn Works.

Amount paid for coal and cannel	£54,591 15 4
Tons of coal, at 12s. 2½d. per ton, to equal this money	89,506 tons.
Carbonizing wages, including stokers, supervision, and scurffing	£11,723 12 11
Carbonizing wages (as above), per ton	0 2 7⁄435

Therefore, the difference in favour of the Rochdale Road station, where half the works is now fitted up with my machinery, is 1-646d. per ton, which means a saving for the year, upon 155,239 tons carbonized, of £5592 10s. 2d.

JOHN WEST,

Late Chief Engineer to the Manchester Corporation Gas Department.

Manchester, July 13, 1888.

MR. HUNT'S CRITICISMS ON MR. CARPENTER'S PAPER.

SIR,—I was rather amused the other day, on reading the good-natured growl of our friend Mr. Hunt, in the *JOURNAL* for the 3rd inst., on Mr. Carpenter's paper read at The Gas Institute meeting; but, unfortunately, in the last paragraph his growl becomes a snarl. As to what he says about Mr. Carpenter's paper I have nothing to say at present; and I fancy Mr. Carpenter, if he likes, and when he likes, can take care of himself. But Mr. Hunt exclaims: "What has London done in the last ten years to bring about this great advancement? What has she contributed to this result?" Mr. Hunt says "Absolutely nothing!"

Now, no doubt it would be interesting to your readers to have Mr. Hunt's replies to the following questions:—Within the last ten years, where were the first workable regenerative furnaces built in the United Kingdom? Where did Mr. Hunt first see such furnaces at work in the United Kingdom? Where was the first paper read, with description and discussion, upon such furnaces, giving experiences of their working, &c., in England?

If my memory serves me right, Mr. Hunt will be compelled to reply to these queries "In London." It was in London where they were first tried. It was in London where they were greatly improved. It was in London where the original errors in construction were eliminated and discarded. It was in London where these furnaces were brought to something near perfection. It is in London where they are being still further improved. And it was from London that the Provinces took their copies of the furnaces. After London had set the example and tried them, but not for years after London had made them successful, did provincial managers begin to use them.

It might be asked, in the same spirit, What has Birmingham done? what has she contributed to this result? I will not be so inaccurate or so uncharitable as to say, "Absolutely Nothing!" but will just turn up the last issue of "Field's Analysis;" and one is tempted to say that Birmingham has not done very much, when the fuel account is compared with London. Birmingham, with a credited make of only 41·7 bushels of coke per ton of coals carbonized, uses 23 per cent. of this low make for fuel in the regenerative furnaces; while taking the last in the list of the London Companies, where Mr. Carpenter's furnaces are partly in use at one of the stations, with a credited make of coke as high as 49·8 per ton, the fuel used is only 20 per cent. of this high make. I fail to see what Mr. Hunt has to crow about, or where he gains by "comparing."

It would be also very interesting to your readers, as well as to myself, if Mr. Hunt would name the towns in England where "10,000 cubic feet and upwards per mouthpiece" are obtained. I like the *upwards*; and hope it may turn out something like the Scotchman's "mile and a bittock." Also if he will state what description of coals are used; the duration of the charges; the size and length of retorts; how long such a make has been sustained consecutively, by the same settings and the same retorts; how long the retorts last, and how often the ascension pipes stop; and what is the profit made and the selling price of gas in such towns—because Mr. Hunt seems to imply that a large make per mouthpiece is evidence of good working. But I can tell him of some towns where the make of gas is only about 5000 cubic feet per mouthpiece, and the gas is sold much cheaper than in Birmingham. I can also tell him of a place where they *once* made 12,000 cubic feet per mouthpiece for three consecutive days; and at the end of eighteen days the whole setting was burnt down. Would Mr. Hunt approve of this straining after high makes per mouthpiece? But, waiting to hear from him the names of the towns with the above particulars where he says they make 10,000 feet and upwards per mouthpiece,

I am, Sir, your occasional correspondent,

A. B.

July 14, 1888.

EUROPEAN GAS COMPANY, LIMITED.—The annual meeting of this Company was held yesterday. Mr. H. McLauchlan Backer presided, and moved the adoption of the Directors' report. He referred in high terms to the manner in which the late Chairman (Mr. W. White) performed his duties during the 40 years he had been a Director, 20 of which he had occupied the chief position on the Board; and he also expressed the deep sympathy which the Board felt with the members of the deceased gentleman's family. Allusion was next made to the success of negotiations which had been in progress for some time for the extension of the concession at Bolbec. This had been secured for 20 years, so that the treaty would not expire until 1926. The aggregate increase in the sale of gas at the seven stations of the Company was 4 per cent. The report was adopted; and a dividend at the rate of 2½s. per paid-up share, and in the same proportion on those not fully paid up (free of income-tax), was declared.

Parliamentary Intelligence.

HOUSE OF LORDS.

TUESDAY, JULY 10.

The Nelson Local Board Bill was reported, with amendments. The Gas Provisional Orders Bills (Nos. 1 and 2), the Gas and Water Provisional Orders Bills, and the Water Provisional Orders Bills (Nos. 1 and 2) were reported without amendment; amendments made; and Bills ordered for third reading.

THURSDAY, JULY 12.

The Gas Provisional Orders Bills (Nos. 1 and 2), the Gas and Water Provisional Orders Bill, and the Water Provisional Orders Bills (Nos. 1 and 2) were read the third time, with the amendments, passed, and sent to the Commons.

PRIVATE BILL LEGISLATION.

A report was presented from the Select Committee on Private Bill Legislation, with the minutes of evidence given before the Committee, together with appendices.

SOUTH METROPOLITAN ELECTRIC LIGHTING BILL.

A Bill to confirm a Provisional Order made by the Board of Trade under the Electric Lighting Act, 1882, relating to certain parts of the Metropolis, was presented by the Earl of Onslow, read the first time (Standing Orders being suspended for the purpose), and referred to the Examiners.

FRIDAY, JULY 13.

The Examiners reported that the Standing Order applicable to the Electric Lighting Order Confirmation Bill had been complied with.

The Local Government Provisional Orders (Gas) Bill was read the third time, with the amendments, passed, and sent to the Commons.

HOUSE OF COMMONS.

MONDAY, JULY 9.

ELECTRIC LIGHTING AT THE HOUSES OF PARLIAMENT.

Sir H. Roscoe asked the First Commissioner of Works whether, in view of the serious deterioration of the stone fretwork of the interior of the Houses of Parliament "owing to the corrosive action of the products of combustion of gas," he would undertake to extend the system of electric lighting throughout the building, so as to avoid the "evil consequences" which attend the present system.

Mr. PLUNKET: To extend the present system of electric lighting throughout the whole of both Houses of Parliament would involve a very considerable expenditure—not less than £40,000—for plant. It would, however, probably effect a considerable saving in the annual cost of lighting the Palace. Before making any proposals upon the subject, it would be necessary to consider whether some more economical way of obtaining the necessary current of electricity than that which we now use may be made available.

TUESDAY, JULY 10.

The Edinburgh and Leith Corporations' Gas Bill (Lords) was reported, with amendments.

THURSDAY, JULY 12.

The Edinburgh and Leith Corporations' Gas Bill (Lords) was read the third time, and passed, with amendments.

The Select Committee on the South Staffordshire Water Bill reported that the parties do not intend to proceed further with the Bill.

The report of the Select Committee on Private Bill Legislation (*vide supra*), was presented.

FRIDAY, JULY 13.

The Falkirk and District Water Bill was read the third time, and passed, with amendments.

The London Sea Water Supply Bill (Lords) was reported, without amendment.

HOUSE OF LORDS COMMITTEE.—MONDAY, JUNE 18.

(Before Earl JERSEY, Chairman; Viscount POWERSCOURT, Lord WINDSOR, Lord MANNERS, and Lord HENRIES.)

HEXHAM LOCAL BOARD WATER BILL.

This Bill, which is to enable the Hexham Local Board to construct new water-works for the supply of the town, was under consideration to-day.

Mr. POPE, Q.C., and Mr. MCRAE appeared for the promoters; Mr. BIDDER, Q.C., and Mr. WORSLEY TAYLOR for Mr. W. B. Beaumont, M.P., who opposed the Bill.

Mr. POPE, in opening the case for the promoters, observed that the question involved would not occupy the Committee for any length of time, although it was of considerable importance to the town and district of Hexham. That district was governed by a Local Board; and the Bill before the Committee embodied a scheme for obtaining a better and more efficient supply of water to the district. As far as he knew, the only point of dispute likely to arise was on the opposition of Mr. W. B. Beaumont, M.P., the owner of the land wherein rose the springs which it was proposed to take for the supply. The character of the district had changed since the existing source had been fixed upon as a good one. Instead of being a wild, unmanured country, the water of which was unpolluted, it had become cultivated and highly manured, with the result that the water was no longer suitable for domestic purposes. From time to time of late years the question of an improved supply had come before the Board. Various schemes had been suggested; and at last the Board determined that they would place the whole matter in the hands of a competent Engineer. They consulted Mr. Hubert Laws, and instructed him to ascertain, by an investigation of the district surrounding Hexham, what would be the source of supply which he would recommend. In October, 1887, he presented a detailed report, in which he pointed out that he had examined five sources of supply, among them being the springs known as the Lade Wells. They were springs rising in a formation of millstone grit, and the area feeding them could, therefore, be easily and accurately defined. The actual drainage area of the springs in question was 1350 acres. Mr. Beaumont, the petitioner, was the Lord of the Manor, and to this extent was interested in the matter. At present there were three springs that issued close together upon the area to which he (Mr. Pope) had referred. The works contemplated were of the simplest character. It was proposed merely to construct a reservoir into which these springs might flow; and thence the supply for Hexham would be drawn. The total yield of the three springs appeared to be about 1,500,000 gallons per day. The present requirements of Hexham were about 250,000 gallons a day, or only one-sixth of the entire amount of the average yield of the springs. Allowing for the natural growth of the population of the district for 20 years to come, the maximum amount that would be required at the end of this period would be only 400,000 or 450,000 gallons a day.

At present all this water ran absolutely to waste. There were no mills on the burn into which the springs flowed; so that there could be no objection to the abstraction of the water on this score. The burn ran into other burns, which fell into a larger river, and ultimately into the Tyne. The promoters were seeking simply to avail themselves, for the purposes of Hexham, of 400,000 or 450,000 out of 1,500,000 gallons of water, leaving the residue—at present useless and not available for anything—untouched. The Lord of the Manor's objection, so far as he could gather, was that he believed there might ultimately be mining operations upon the moorland where the springs arose. All he (Mr. Pope) could say in reply was that there never had been any user of the water for mining purposes; that there seemed to be no immediate prospect of its being wanted for such purposes; and, in any case, that if it should be so required there would be plenty available, because the Local Board proposed to restrict themselves to such quantity as would be sufficient for present requirements, and for such a time forward as their Lordships might deem reasonable. The Local Board had approached Mr. Beaumont in every possible way, and had tried to deal with him in the most conciliatory manner. During the negotiations, Mr. Beaumont, he was informed, expressed a desire that the opinion of some independent engineer should be taken; and intimated that if it was found that the scheme was really one for the benefit of Hexham, he would be willing to assist rather than impede it. Accordingly, the whole question was referred to Mr. J. R. Forster, Engineer of the Newcastle and Gateshead Water-Works, who, almost in the capacity of a referee between the parties, examined into the scheme which had been presented by Mr. Laws. He reported that the springs appeared to be permanent, and likely to produce a superabundance of water, not only for present requirements, but for those of many years to come. Mr. Forster added that this was the best available source of supply for Hexham; that the necessary works could be carried out at comparatively little cost; and that the water itself was of undoubted purity. If the Committee sanctioned the scheme itself, there would be no objection on the part of the promoters to ample provisions being inserted for Mr. Beaumont's protection, and for securing him compensation for the abstraction of water rising within his property.

Mr. Robb, Chairman of the Local Board, then gave evidence in support of the Bill.

TUESDAY, JUNE 19.

On the resumption of the proceedings this morning, Mr. Fenwick, M. Inst. C.E., of Leeds, and Mr. G. H. Hill, M. Inst. C.E., of Stockport, gave evidence on behalf of the promoters; the former witness stating that the water of the Ladle Wells was the best that could be found in the district, and the latter expressing the opinion that 25 gallons per head per day, as proposed, was an ample supply of water for a town like Hexham.

Mr. BIDDER, in addressing the Committee in opposition to the Bill, admitted that, in a certain sense, the water proposed to be taken was running to waste; but the prospect of mineral working in the locality was by no means so visionary as had been suggested. There was a perfectly reasonable belief that sooner or later the lead veins, of which indications had been noticed in various places in the district, would be worked; and to take away the water that would be required for dressing the mineral would be to absolutely prevent the development of these works. The history of the water supply showed that the Ladle Wells scheme was a mere caprice of the Local Board, taken up at the very last moment, and decided upon within a month or five weeks of the first suggestion with regard to it being made. He contended that, if a new source of supply was necessary at all, there was another—the Stubly Syke source—which would be ample and satisfactory.

The room was then ordered to be cleared. On the re-admission of the parties,

The CHAIRMAN said the Committee were satisfied that the preamble of the Bill had been proved, and that the measure should be proceeded with; but they would require provisions to be inserted limiting to 350,000 gallons per diem the quantity of water to be drawn from the Ladle Wells.

Mr. WORSLEY TAYLOR observed that he would have to bring up certain clauses for the protection of Mr. Beaumont. There was, for instance, a question as to limiting the supply in times of drought or other circumstances. It might not be necessary for the promoters to take the whole 350,000 gallons every day; and there was something to be said as to the possible effect on the springs in dry periods.

The CHAIRMAN said it must be understood that no considerations as to drought, &c., would affect the decision of the Committee to allow the promoters to take 350,000 gallons per diem.

After an adjournment, to allow of the terms of the Committee's decision being considered,

Mr. WORSLEY TAYLOR brought up a clause providing that on no one day should more than 350,000 gallons, as measured by a gauge, be taken from the springs.

A discussion followed as to the clause imposing a penalty of £10 per day upon the Local Board for taking more than the prescribed quantity of water. The Committee decided to reduce the penalty to £5; and, with some minor alterations, they passed the Bill.

CROMER WATER COMPANY, LIMITED.—The tenth annual general meeting of this Company was held on Monday last week, under the presidency of Mr. B. Bond-Cabell. The report of the Directors stated that the water and meter rental amounted to £658 11s. 2d.; showing, as compared with last year, an increase of £92 17s. 8d. The expenses were £362 1s. 1d.; being an increase of £75 6s. 5d. The profit for the year amounted to £306 11s. 1d., which, added to the balance brought from the last account and the bank interest, made the total of the profit and loss account £455 14s. 8d. After paying interest and certain other charges, there was left £293 12s. 4d. available for division. The Directors recommended a dividend at the rate of 3 per cent. per annum, free of income-tax, which would absorb £254 14s., and allow a balance of £38 18s. 4d. to be carried forward. The report was adopted.

NEW JOINT-STOCK COMPANIES.—The following joint-stock Companies have just been registered:—The North Walsham Gaslight and Coke Company, Limited, with a capital of £6000, in shares of £10 each, to acquire the business now carried on by the North Walsham Gaslight and Coke Company, and the whole of the real and personal property belonging to the Company. The Westminster Electric Supply Corporation, with a capital of £100,000, in shares of £5 each, of which 100 are to be founders' shares, and the remaining 19,900 ordinary shares, with the object of carrying on, either in the City of Westminster or elsewhere, the trade or business of electric lighting. The Barnoldswick Gas and Light Company, Limited, with a capital of £12,000, in £10 shares, with the object of manufacturing and supplying gas or other illuminating power in the parish of Barnoldswick, York, and generally to carry on business as gas and electrical engineers, and every other business connected with the manufacture of gas and electricity.

Legal Intelligence.

HIGH COURT OF JUSTICE—CHANCERY DIVISION.

FRIDAY, JULY 13.

(Before Mr. Justice KAY.)

BRAY v. GANDON AND OTHERS.

This motion came before the Court this morning, and was quickly disposed of.

Mr. MARTEN, Q.C., appeared for the plaintiff; Mr. RENSHAW, Q.C., for the defendants.

Mr. MARTEN said the defendants were Mr. Gandon and others, who were sued on behalf of themselves and others, the officers and members of the Council of The Gas Institute; and the motion asked for an injunction to restrain the defendants from excluding the plaintiff from the meetings of The Gas Institute, and from interfering with him in the enjoyment of his privileges of membership and benefits in the property of the Institute until trial of the action or further order, and that the defendants might be ordered to pay the costs.

Mr. RENSHAW, Q.C., said he appeared for the defendants—the Council of The Gas Institute. The question was one as to there being the requisite majority of votes at a meeting; and, in fact, it turned on the question whether a majority could be constituted by two-thirds of a man. The case appeared to him to be governed by that of *Labouchere v. Lord Wharncliffe*; and, under the circumstances, as the defendants were probably, under that decision, in the wrong, they were willing to submit to a declaration in the terms asked for by the writ, to the injunction, and to pay the costs of the action.

Mr. MARTEN said he understood the defendants were willing to treat this as the trial of the action.

Mr. RENSHAW assented.

Mr. MARTEN said he only had to ask further for an order that the persons who had been allowed to defend on behalf of the Institute should be ordered to pay the costs of the action.

Mr. RENSHAW said he did not object to that.

His Lordship made the order accordingly.

SURREY SESSIONS.—WEDNESDAY, JULY 4.

(Before Mr. H. Yool and a Jury.)

SOUTHWARK AND VAUXHALL WATER COMPANY v. LINSEY.

CHARGE OF UNLAWFULLY TAKING WATER.

In this case the prisoner was charged with stealing a quantity of water, the property of the Southwark and Vauxhall Water Company. From the evidence it appeared that in August, 1886, the water to the prisoner's house was withdrawn for non-payment of rates; and since that date the Company had no knowledge whence he was obtaining his supply. They endeavoured to find out; and eventually it was ascertained that he was surreptitiously taking water from the cistern of a house adjoining his own. The matter came in the first instance before the Magistrate at the Southwark Police Court (see *ante*, p. 30); and Mr. Linsey declining to submit to his Worship's decision, was committed for trial.

Mr. LUSHINGTON appeared for the complainants; Mr. AVERY defended the prisoner.

Evidence having been given as to the disconnection of the water service at the prisoner's house,

Mr. J. Pickles said that he was a private detective; and on the 7th of June last he, in company with another officer, kept watch on the cistern supplying the house No. 441, Old Kent Road. At about 11.30 at night someone approached this from prisoner's house, and affixed a hose to the pipe supplying this cistern. On the appearance of a light, however, at one of the houses, the person beat a retreat; taking the hose away. When all was clear again, someone refixed the hose shortly afterwards, and water then ran into the prisoner's butt for ten minutes. In the darkness he saw a hand attempting to withdraw the hose, which he seized. There was a slight struggle, and the other officer identified the prisoner by means of a light. He told Linsey he would be charged with stealing the water; and he replied, "I am done; make it as light as you can on me."

Lane, the companion of the previous witness, corroborated his evidence.

Mr. AVERY contended that it was no offence at criminal law to take water. There was no distinction between water and air; it was free to everybody. Besides, it would have to be proved that stealing water was a larceny; and the only authority they had for this was the decision of two Judges of a Divisional Court, who decided that obtaining a supply surreptitiously was a misdemeanour, but that, however, was in a case where the parties had no statutory powers like those of the present complainants. He further argued that the water belonged to the owner of the house No. 441, Old Kent Road, who, if anybody, was the party aggrieved, and certainly not the Water Company. Therefore, if the case was a subject of larceny, it could not be held that the Company were parties who had suffered any loss. The offence with which his client was charged was not an indictable one; and he was of opinion that proceedings should rather have been taken under one of the Company's Acts of Parliament, for which, on a case being proved, there was a penalty of £10.

Mr. LUSHINGTON held that the Company contracted to supply water simply to No. 441, Old Kent Road, for which a rate was charged, and that the prisoner had no right to obtain his supply from that house. It was proved that Linsey had stolen the water, and had never paid for any since 1886. If his learned friend's argument was right, any householder could supply a whole row of houses, without their occupiers paying a farthing for it. Then the jury should bear in mind that Linsey had been obtaining a surreptitious supply for nearly two years. It was clearly not within his right to do this.

Mr. Yool, in addressing the jury, recapitulated the facts as given in evidence, and said there was really no dispute about them. Prisoner was caught in the act of taking the water, and when arrested said he was "done," and admitted that for two years he had been getting his supply from the next house. Upon the evidence given and the admissions that had been made in Court, the prisoner was not justified in taking a supply of water from No. 441, Old Kent Road; and he (Mr. Yool) should direct the jury to pay no attention to what had been alleged—that when the water passed into the pipe at No. 441, it became the property of the owner of that house, because, as a matter of law, it was decidedly the property of the Water Company supplying it. Having regard to the decision given by two of Her Majesty's Judges in a similar case, he held that water passing through the Company's mains was their property; and anyone taking it, as the prisoner had done, was guilty of larceny. The Company had their obligations to meet; and it was absurd to suppose that a person who took their water should not be liable to punishment for so doing.

Mr. AVERY here contended that proceedings should have been taken under the Company's regulations, by which penalties could be inflicted; and he further argued that stealing water was not an act of larceny.

Mr. LUSHINGTON: That is a mere statutory right which does not take away our remedy at Common Law.

Mr. Yool, after perusal of the Company's Acts, said he would leave to

the jury the points argued. The house in question had been without water for nearly two years; and the way in which the prisoner obtained his supply was undoubtedly an attempt to procure water without paying for it, and thus to deprive the Company of their rights. If the jury found that the prisoner stole the water with the intention of defrauding the Company, then he was guilty of misdemeanour.

After some deliberation, the jury gave a verdict that the prisoner was guilty of taking the water, but not with a felonious intention.

Mr. YOOL (with surprise): That, gentlemen, practically amounts to a verdict of "Not guilty."

Mr. AVERY asked that the verdict of the jury be recorded.

Mr. YOOL said he should have to discharge the prisoner; and he hoped it would be a lesson to him and others not to take water which did not belong to them. He afterwards addressed the jury, stating that he could not account for their decision, as, if the prisoner had no intention of doing wrong, he would not have gone at midnight to obtain his supply of water in the manner he had done, and certainly would not have retreated when a light appeared at a neighbouring house. This very act was conclusive that the prisoner had guilty intentions.

CITY OF LONDON COURT.—FRIDAY, JULY 13.

(Before Mr. Commissioner KERR and a Jury.)

SCRIMGEOUR v. THE NEW RIVER COMPANY.

A QUESTION UNDER THE CONSTANT SUPPLY REGULATIONS.

This was an action which raised a rather important question to water companies and consumers, especially in regard to constant supply. The plaintiff, Mr. Walter Scrimgeour, stockbroker, of Old Broad Street, E.C. sought to recover the sum of £5 10s. from the defendant Company for damages he had sustained at their instance.

Mr. M'CAUL appeared for the plaintiff; Mr. G. LYON for the Company.

Mr. M'CAUL, in opening the case, said the question in dispute was not one of amount; and the decision would affect many persons residing in the same neighbourhood as the plaintiff at Highgate. This district was supplied by the New River Company with water under the Water-Works Clauses Act, 1847. The powers of the Company anterior to 1871 were these: Under the general Water Act and their own Private Acts, every person who provided fittings and put in a communication-pipe and made application to the Company was entitled, as a matter of right, to have a supply of water to his premises. This was an intermittent supply, which would last about half an hour or an hour. In 1871, the Legislature considered that in certain cases water companies should be compelled to give a constant supply; and, accordingly, by the Metropolis Water Act of that year, it was provided that, where the local authority demanded a constant service of water, or where the Company thought it necessary, then it should be given, provided that the Local Government Board considered it was really requisite. Under that Act, in 1887 the New River Company determined that a constant supply of water should be given to the plaintiff's district; and on the 12th of May last year, they served notices upon all the consumers in Highgate (and amongst others the plaintiff) to this effect. The notice recited that the St. Pancras Vestry had required them to give a constant supply, and it directed the plaintiff to effect alterations in the fittings of his house, in the manner prescribed by the notice, from the top to the bottom of the house; the fittings to be such as would suit the constant service. Whether he liked it or not, he was bound to comply with the notice, under serious penalties, which could be recovered in the Police Court. The alterations were made, and the Company's Inspector on the 15th of September went over the house to see the whole of the fittings; and he approved of them. The plaintiff then waited for the constant supply. Three months passed; and on the 9th of March the plaintiff's solicitors wrote to the Company, asking what they meant by having compelled the plaintiff to incur expense, and then not put on the constant service. On March 10 the Secretary of the Company wrote to say the subject would have due attention; and upon being pressed, on the 19th of March, by the plaintiff's solicitors for an explanation, they gave a constant supply to the lower part of the house, and afterwards wrote declining to give it to the upper part. Thereupon the present action was brought to recover £5 10s., the money paid for the fittings, which were now rendered useless. The learned Counsel submitted that the plaintiff was either entitled to a constant supply in the upper part of the house or to the payment of the money expended in carrying out the instructions of the Company contained in their notice.

Mr. LYON submitted that the question in dispute was one of law and not of fact.

Commissioner KERR thought the jury had better be discharged.

Just as this course was about to be decided upon, the learned Counsel could not agree upon it, and the whole case was proceeded with.

The plaintiff was called to substantiate his case; as was also his plumber, Mr. Barber. The last witness was cross-examined at some length as to the way in which the work was done.

Mr. LYON, in addressing the jury, said The Grove, Highgate, where the plaintiff lived, was the highest part in that locality. The Company were not compelled by any Act of Parliament to afford a constant supply to anything like the height of the plaintiff's house. They were not bound to give a constant supply to a higher level than 370 feet above Trinity high-water mark—that was to say, a level of 300 feet, and then 70 feet more for the supposed height of any house. The house in question was, in fact, 66 feet, as he would show, above this level; and accordingly the Company were not compelled to afford a constant service of water.

Mr. M'CAUL: They should have known this before giving notice.

Mr. LYON said he should submit that the Company had fulfilled their contract. They had, in effect, provided a constant supply of water for this house; but it was practically impossible to give a constant service to the upper cisterns in the house. They had done everything in their power, and found it could not be accomplished. He contended that they were entitled to call upon the plaintiff to make every alteration which he had made without any question of constant supply at all. They had given the plaintiff, with pumping day and night, something more than an intermittent service, for the water was pumped into the upper cistern from six in the morning until noon. This was simply to meet the requirements of a closet and a tap for jugs, &c.; there being no bath upstairs.

Commissioner KERR: Plaintiff says, "I paid my money for a constant supply. I altered the fittings at your request, and you approved them. If you had told me I could not have the supply to the upper floor, I might have abolished the water supply altogether."

Mr. LYON: He has not paid his money for a constant supply. He has paid his money in order that he might have his fittings put into the condition we required them to be in.

Commissioner KERR: With a view to a constant supply.

Mr. LYON: Oh, no. The notice commences by saying we "propose" on a certain day to give him a constant water service for these premises; and we go on to give him notice that he must put his fittings in order in accordance with the regulations made—not by us, but formerly by the Board of Trade and now by the Local Government Board. These are

fittings which every house is compelled to have if the Company chooses to require them, whether the supply is intermittent or constant.

Evidence was then called on behalf of the Company as to the height of the house above Trinity high-water mark; and two waste inspectors spoke to having examined the house.

Commissioner KERR summed up by telling the jury the case was eminently one for them.

The jury gave a verdict for plaintiff for the amount claimed; and judgment was entered accordingly, with costs on the higher scale. Leave to appeal was refused.

MARYLEBONE POLICE COURT.—MONDAY, JULY 2.

(Before Mr. DE RUTZEN.)

THE CHARGE FOR WATER FOR PAROCHIAL PURPOSES.

To-day the matter in dispute between the Paddington Vestry and the West Middlesex Water Company, as to the charges made by the Company for water supplied for parochial purposes, which was decided by the Court a short time since,* again came before his Worship.

Mr. MEAD contended, on behalf of the Vestry, that the decision of the Magistrate that the parish should pay the Company 8½d. per 1000 gallons had reference to the water used for the finishing of sewers as well as for that required for the watering of roads.

Mr. POLAND argued, for the Company, that the decision was only as to the watering of the roads.

Mr. DE RUTZEN said he was under the impression from the first that the point he had to decide was as to the watering of the roads only; and his decision was exclusively as to that point. If there had been any misunderstanding, and the parish were not satisfied, a fresh summons would have to be taken out.

Mr. MEAD said the Company had threatened to cut off the supply; and, if the threat were carried out, it would be a serious matter.

Mr. POLAND said the Company would not think of doing that.

NORTHERN COAL TRADE.—The steam coal branch of the northern coal trade is active—the demand being large, and the production good; but the prices have not yet shown the advance which some hoped they would have done. Steam coal is quoted 7s. 9d. for best quality, and thence down to 6s. 9d. for second kinds. Small coal is rather slower in sale; or, rather, the production is a trifle in excess of the demand. For gas coal, the demand just now is slightly increasing; but it is much below the normal amount. Some large local contracts for gas coal are in the market. Household coal is still weak, and the price droops; but there is a good inquiry for manufacturing coal. For coke the demand is brisk; and the exports to Spain are increasing.

BRADFORD WATER SUPPLY.—At the meeting of the Bradford Town Council last Tuesday, a long discussion took place on the subject of the water supply of the borough, especially with reference to a proposal to supplement the present sources by a scheme which has been prepared by the Water Engineer (Mr. A. R. Binnie, M. Inst. C. E.) for utilizing certain water at Grimwith. On analysis this water has been pronounced to be dangerous on account of its action on lead; and a sample is now in the hands of a London analyst, who is testing its liability to contamination from this cause. Apart from this, there are legal difficulties which will interfere with the carrying out of the Grimwith scheme, some of the mill-owners affected by it having made enormous demands for compensation. Elaborate reports by the Water Engineer, the Borough Analyst (Mr. Rimmington), and other gentlemen who have analyzed the water, have been published in a local paper; and altogether the matter is exciting considerable interest. Fortunately there is no dearth of water in Bradford just now; the quantity in store in the high-level reservoirs being sufficient to last till the beginning of November, and that in the low-level reservoirs till Dec. 1 next.

THE CHARGES IN CONNECTION WITH THE HALIFAX COAL CONTRACTS.—Mr. Ellis Lever has written to the Town Clerk of Halifax (Mr. Keighley Walton) the following letter on the subject of the charges which have lately been made in connection with the coal contracts of the Corporation of that town:—"Dear Sir,—I have not yet received any acknowledgment from you of the receipt of my letter of the 5th inst. [see ante, p. 79]. I am going to Germany for a few days; and on my return it will give me pleasure to meet you, and afford you all the information in my possession, on the distinct understanding that it shall be considered as privileged, and not made use of or published except as I suggest. The attitude of some members of the Corporation will, I feel sure, be changed after the inquiries which, in my opinion, ought to be instituted." Mr. T. Fox, of the Silkstone Coal Company, has also written to the Town Clerk declining the offer made by the Council at their last meeting. The resolution of the Council, it may be remembered, was "that Mr. Fox be informed forthwith that if the person referred to in his letter of the 2nd of June be a member of the Council or a servant of the Corporation, his offer to prove his charges, on being indemnified against costs, be accepted; it being understood that such charges shall be proved in a Court of Law." Mr. Fox's letter has not been published; but the *Halifax Courier* says he still adheres to the statements and offers in his previous letters to the Town Clerk.

THE ELECTRIC LIGHTING SCHEME FOR BRADFORD.—The Bradford Corporation, in view of their scheme for erecting a central generating station for providing a regular supply of electric lighting and power, have recently issued a circular to occupiers of business premises in the central portion of the borough, inquiring whether such occupiers would be disposed to take a supply of the current regularly for a stated period—suggested as three years. So far there has been a fair response to the inquiry, though it is somewhat early to enable the Corporation to say to what extent the experiment is likely to succeed. In addition to places of business, the Free Library, the markets, and other public buildings are to be provided with electric light. It is proposed to make the supply continuous except between one a.m. and five a.m., unless otherwise arranged. With respect to price, the Corporation have determined to adopt an alternative system of charge for incandescent lamps—viz., (1) 5d. per unit, the Corporation to supply meters, if desired, at a rental of 10 per cent. on the cost; (2) by an annual charge of 20s. per lamp of 16-candle power, irrespective of the actual hours of lighting. The charge for the supply to arc lamps is to vary with the illuminating power of the lamps as required by the consumer at the rate of 5d. per unit. Ten units with incandescent lamps of 16-candle power produce an amount of illumination equal to about 1000 cubic feet of 15-candle gas. It is pointed out that the price is unavoidably higher at first than gas at its present low rate in Bradford. But against this are to be set the advantages which it is stated the electric light has over gas. The Corporation propose to carry the supply up to the buildings; the internal fittings being provided by the consumer.

* See JOURNAL, Vol. LI., p. 828.

Miscellaneous News.

PARA GAS COMPANY, LIMITED.

An Ordinary General Meeting of this Company was held last Thursday, at the London Offices, 16, St. Helen's Place—Mr. ROBERT MORTON in the chair.

The SECRETARY (Mr. T. S. Borradaile) read the notice convening the meeting, and it was agreed to take as read the Directors' report and accounts for the half year ending March 31 (see *ante*, p. 80).

The CHAIRMAN, in moving the adoption of the report and accounts, said that but for their being in a position to declare a dividend, there would have been no meeting called that day. The working for the half year under consideration had been much more satisfactory, he thought, than in any similar period the Company had had for a number of years past. The report said that the revenue for the six months was slightly in excess of that during the previous half year, but somewhat less than the corresponding period of 1886-7. This was, however, more than accounted for by the discount of 10 per cent. which had not been allowed during the half year under consideration, which was not allowed during the corresponding period of 1886-7. The private lighting did not increase as the Board could wish, or as he had hoped it would. The Company were, as had been said before, in severe competition with kerosene; and the beautiful lamps they now had, and the excellent light which these lamps gave from kerosene, induced people to use them in preference to gas. The consideration of means to alter this state of things was constantly before the Directors; and they had evidently not succeeded by the reduction in price, or rather the discount, in doing very much. Their Managers had written to the Directors on the subject; and they hoped they might be able to do something shortly which would bring back to the Company some of the old consumers, who were using kerosene while they had all the gas-fittings in their houses, and perhaps add to the number of consumers. The second paragraph in the report showed that the expenditure had been considerably reduced in some of the most important items; and the result was a profit of more than £6400 on the half-year's working. The heavy expenditure on repairs, which was necessitated by the state of the works some three or four years ago, had practically ceased; and they were informed that, notwithstanding the comparatively small amount charged for repairs in the half year—£216 9s. 8d., as against a sum of £1000 in the preceding half year, and he thought nearly £1700 in the half year previous to that which corresponded with the one under consideration—the Manager reported that the works and the property of the Company were in good condition. Perhaps the most important paragraph in the report was that which referred to the change in the management. Mr. Hall, who, as reported at the last meeting, took charge of the works on the 2nd of August, 1887, elected to come home on the termination of his agreement with the Company. He had been three years in Pará; and he (the Chairman) might say it was a great disappointment to the Directors when he informed them that he intended returning to England at the end of his engagement. He had shown such energy and was doing so well, that they were hopeful he would continue. Although a very liberal offer was made to him, he declined it at the time. He afterwards, however, regretted it, and wrote saying that he would accept the terms offered, and remain for another three years, or, at all events, until such time as the petition to the Imperial Government, which the shareholders had before them at the last meeting, was settled in some way or other. The Board had, however, by that time engaged a successor to Mr. Hall; and he had now come home. They had obtained some valuable information from him with regard to the position and working of the Company. In his place, as they saw, Mr. J. Gibson Newbigging had been appointed. He was the son of Mr. Thomas Newbigging, of Manchester—a man well known in the gas world, and who was himself for some years, a Manager in Brazil, and a successful Manager. His son was at that time a lad, and was quite conversant with the Portuguese language, which, however, he had lost before he went away. The Board hoped that, having had a knowledge of it when he was younger, it would help him in re-acquiring it. He wrote hopefully of the concern, although at the same time evidently appreciating the difficulties he had to contend with; and the Directors were hopeful that what he was doing would result for the benefit of the Company. The next paragraph in the report referred to the petition which he had already mentioned; and the amount of routine and red-tape which was attached to all these things was very harassing and disappointing to the Board. It seemed that it could not be pushed forward faster than had been done. They would notice that the repayment of duties had received the attention of the Provincial Government; and a speedy settlement of this matter was anticipated. The Board hoped nothing would come in the way to prevent it. Then they referred again in the report to the fines. He (the Chairman) was tired of speaking about this; but the Provincial Government were evidently not tired of inflicting them; and they went on from month to month in a way which—well, he had characterized it several times before, and he did not intend to refer further to it than to say, that the vigorous action which Mr. Hall took before he came home was about to be repeated by their new Manager—Mr. Newbigging—and whether this would result in anything more beneficial to the Company than the last remained to be seen. The question of a new contract continued very much as it was when the shareholders last met. The agent in Pará, who was working it for the Company, was at present in this country, or on his way to it; and the Directors hoped to see him, and learn something more definite as to the prospects of its passing the Assembly either sooner or later. In conclusion, he need scarcely say he was pleased to be in a position to propose a dividend, though it was a small one. He begged to move—"That the report and accounts of the Directors to the shareholders, as presented, be and are hereby approved and adopted."

Mr. A. H. HENRY seconded the motion. He observed that there was one question to which the Chairman had not drawn attention, and that was the exceptional expenditure the Company were liable to, compared with English Companies, in providing houses with gas-fittings, which they were obliged to do. They did not get much credit for this, and had to write off a large amount for it.

Mr. G. BLUNDELL remarked that the question of fines seemed to come up at all their meetings; and he thought it would be well if the Chairman would give the shareholders some information as to this matter, so that they might have some idea as to what steps should be taken to protect themselves from them. It was difficult for the Board to deal with this question, because the Provincial Government seemed to have some sort of arbitrary power which it was hard to fight. If the matter was put a little more prominently forward, to show the basis of the claims, he thought perhaps it would go some way to open the eyes of the shareholders on this side as to what, as the Chairman said, was something permanent, and something which the proprietors considered as most unjust.

The CHAIRMAN said he did not think Mr. Blundell could have been at the last meeting. The matter he referred to was fully put before the shareholders then, in considering the petition which was addressed to the

Imperial Government at Rio. The Secretary had just handed him a report of that meeting, which contained an extract evidently from the report of their Manager, and he might first mention that there were some three or four men called Rondas, who went round, in the interests of the police, every night. They were supposed to go round; but whether they went or not, they made statements which caused the infliction of fines. In the report to which he referred, the Manager said:—"We also found the Police Rondas inspecting the illumination of certain streets from corners thereof, considering, when one lamp happens to be a little farther apart than its neighbours, that between these there must be a lamp out, which is duly noted—'Tab Street, three lamps out'—and the Company is fined. On these occasions, I have insisted on seeing the lamp without the light, and found that not even a lamp-post existed. On other occasions we have had the greatest difficulty in convincing the Police Rondas that the lamp in front of the Café Chic, Largo de Polvora, could not be considered a public lamp out, nor those of the Company's station in Estrada Independencia as public lamps with small lights, seeing that in both instances they belong to private parties and consume kerosene." The Company had had no complaint for three years as to the quality of the gas. It was simply as to small lights and lights extinguished. All the lamps might be fully alight at seven o'clock at night, and then five minutes afterwards, through a tropical shower, half of them might be out. They considered that this was a circumstance over which they had no control. At the same time they were not allowed the benefit of it; and were fined accordingly. It was not only for the small lights, but what the Rondas, who had no technical knowledge, chose to fine for.

The motion was then carried unanimously.

The CHAIRMAN moved the declaration of a dividend at the rate of 7 per cent. per annum (less income-tax) on the £5 per share called up on the preference shares for the half year ending March 31, to be payable on the 1st of August.

General TUPPER seconded the motion, which was agreed to.

The CHAIRMAN moved that a dividend at the rate of 4 per cent. per annum (free of income-tax) on the ordinary shares of the Company be declared.

Mr. HENRY seconded the motion and it was adopted.

Mr. ENNIS, in moving a vote of thanks to the Chairman and Directors, said the accounts obviously showed a great improvement. They obtained a dividend larger than they had received for a number of half years past; and a more gratifying fact was that the dividend might have been at the rate of 8 per cent. per annum, but the Board had judiciously kept it at the lower figure.

The CHAIRMAN briefly replied; and said he was sorry the Board felt so impotent, being so far from the seat of operations. They could not help this, however; but would endeavour to do the best they could under the circumstances.

EDINBURGH AND LEITH GAS COMPANY.

The Annual Meeting of this Company was held on Monday last week—Ex-Bailie TAWSE in the chair.

The TREASURER (Mr. J. S. Gibb) read the Directors' report, which stated that, after deducting £15,000 for dividend declared, the year began with a balance in its favour of £8253 5s. 4d. As it was expedient, while the negotiations for transfer were in progress, to keep the business profits for the year to May 15 last intact, the Directors took from this balance, towards meeting parliamentary expenses, £1121 17s. 2d.; leaving £7131 8s. 2d. to be carried forward. The net profit on last year's business was £26,313 16s. 1d. These two sums gave a gross amount of £93,445 4s. 3d. From this, the Directors recommended that a dividend at the rate of 10 per cent. per annum, free of income-tax, be declared—one-half to be payable on Aug. 1 next as usual; and, in view of the transference of the Company to the Corporations, and the terms of that transference, the balance at such time as the Directors may afterwards appoint. Before bringing out the above balance on the year's transactions, there had been deducted the whole year's expenditure, including a full allowance for the maintenance, repairs, and replacements of works and plant, as well as for all other outlays chargeable against revenue. The parliamentary expenses could not be ascertained as at May 15, beyond what is mentioned above; and therefore remain to be met. The Directors desired also to draw special attention to the Manager's report on the excellent state of the works and plant, as indicating the principal causes, combined with economy in management, of the highly gratifying results of the year's business. These results the Board acknowledged were very largely due to the foresight, skill, and professional capacity of the Manager. The Directors recommended that, in view of the winding up of the Company, the accounts that have been kept under the heading of the tear and wear fund, the meter renovation fund, and the accident insurance fund, together with the net balance brought forward at the beginning of last year, being profits of former years that have been expended on the works and plant of the Company, and are now represented by works and plant and not by cash, should be closed and adjusted. This will not at all interfere with the profit of the year now closed; while the balance will then be about met by cash at the bank, or by debts due to the Company. Referring to the transfer of the works, the Directors said that, after a year of much anxiety and very difficult and delicate negotiations with the Corporations of Edinburgh and Leith as to the acquisition of the Company's undertaking, an agreement had been come to within the last fortnight which they regarded as fair and reasonable for both parties. If the Bill of the Corporations was passed as now proposed, the works would be under their charge as from Aug. 1 next; but the Company would continue for the purposes of winding up.

In his report, the Manager (Mr. F. T. C. Linton) first referred to the extensions and additions at the works, authorized in the spring of last year. These, he stated, were finished in the autumn; and the re-construction of the works which the Board had had steadily in view for the past five years, was thereby completed. The works were now equipped throughout with apparatus and plant of the newest and most approved description. They were capable, at the present moment, of dealing with a largely increased manufacture of gas; and for a very moderate expenditure, they could be made adequate for double the present business of the Company. The result of the reconstruction had been to reduce, year by year, the cost of the manufacture of gas. During last year the whole of the manufacture was for the first time effected with the improved apparatus; and therefore the economy arising therefrom could now be exactly ascertained. In the year 1883-4—the year prior to the commencement of the reconstruction—the cost of each ton of coal carbonized was 15s. 2d., and the cost per ton for the manufacturing charges was 6s. 10d.; making for coal and manufacturing charges 22s. per ton. During the past year these costs had been 11s. 1d. and 5s. 8d. respectively; making for coal and manufacturing charges 16s. 9d. per ton, and showing a saving of 5s. 3d. per ton of coal carbonized, as compared with 1883-4. The quality of the gas supplied to the public was 26.69 candles on an average in 1883-4, and during the past year 28.13 candles; so that the reduction in cost had been coincident with an increase in quality to the extent of 1.44 candles. This saving was not

due to any reduction in the price of coals, as the prices of individual coals were generally higher in 1887-8 than in 1883-4. It was entirely owing to the new carbonizing plant, permitting certain cheap canal coals to be largely used (which, with the ordinary retorts, could be used only to a very limited extent), and to the saving of labour with the new apparatus. On the quantity of coals used (39,744 tons), the saving amounted to £10,433, and showed, in a very striking manner, the wisdom of the policy adopted by the Board of keeping the works abreast with modern improvements. The other works and plant were in a thoroughly efficient condition, as regards the gasholders, main-pipes, and service-pipes. This was amply proved by the continued reduction in the quantity of unaccounted-for gas. In the past year this was only 7.63 per cent of the gas made.

The accounts showed a total charge of £234,720 14s. 11d. The gross revenue was £79,058, of which £64,620 16s. 2d. was derived from the sale of gas and meter-rents, and £14,438 16s. 4d. from the sale of residual products. Coals and lime cost £23,225; and the maintenance of works and plant, with replacements, £4047 14s. 2d. The heritable property and works and plant, with meters, were stated at the value of £204,905 4s. 1d.

The CHAIRMAN, in a speech of some length, moved the adoption of the report and balance-sheet.

The DEPUTY-CHAIRMAN (Mr. C. S. Chalmers) seconded the motion, which was unanimously adopted.

On the motion of the CHAIRMAN, the provisional agreement between the Company and the Corporations was unanimously approved.

Mr. W. WHITE moved, and Mr. R. A. LOCKHART seconded, that a special vote of thanks be awarded to the Directors for the manner in which they had conducted the negotiations with the Corporations.

The proceedings then terminated.

METROPOLIS GAS SUPPLY.

The Chief Gas Examiner for the Metropolis (Dr. Williamson, F.R.S.) has presented his report on the quality of the gas supplied by The Gaslight and Coke, the Commercial, and the South Metropolitan Companies, during the quarter ending June 30. The following is an abstract:—

I. *With respect to Illuminating Power.*—The average illuminating power, in standard sperm candles, at each of the testing stations, was as follows:—

The Gaslight and Coke Company—	
Jewry Street, E.C.	16.5
Kinghorn Street, E.C.	16.7
Dorset Buildings, E.C.	16.8
Ladbroke Grove, W.	17.7
Devon's Road, E.	16.8
Carlisle Square, Chelsea	16.5
Camden Street, N.W.	16.3
Graham Road, E.	16.5
Kingsland Road, E.	16.9
Spring Gardens, Charing Cross, S.W.	16.5
Grove Gardens, Regent's Park, N.W.	16.7
Lambeth Road, S.E.	16.5
Millbank Street, S.W. (canal gas)	20.8
Commercial Gas Company—	
Wellclose Square, E.	16.5
Parnell Road, E.	16.5
South Metropolitan Gas Company—	
Hill Street, S.E.	16.5
Foster Place, S.W.	16.2
Stoney Lane	16.4
Lewisham Road, S.E.	16.3
Blackfriars Road	16.2

It will be seen from these results that the average illuminating power has been higher than the parliamentary standard at all the testing stations, more especially at the Ladbroke Grove station of The Gaslight and Coke Company.

II. *As regards Purity.*—Sulphuretted hydrogen has not been present in the gas at any of the testing stations. The average amount of sulphur in other forms than this was considerably less than that allowed—viz., 17 grains—at all the testing stations, especially at the Devon's Road station of The Gaslight and Coke Company, and the Parnell Road station of the Commercial Gas Company, where it averaged less than half the quantity permitted. Two or three slight excesses of sulphur were reported during the past quarter at the Foster Place and the Blackfriars Road stations of the South Metropolitan Gas Company. Ammonia was generally present at all the testing stations (excepting those of the City of London) more or less frequently during the quarter, but only in slight quantities. On no occasion was there any excess.

GAS v. ELECTRICITY.—The *Electrical Review* says: "It is always being said that big gas companies are not afraid of the electric light; but a letter which The Gaslight and Coke Company has sent to the Kensington Vestry with reference to the Town Hall, which is proposed to be lit with the electric light, points rather to the contrary. They have written to the Vestry suggesting that an improved system of lighting and ventilating the Town Hall by means of gas should be tested, and offering to defray the cost of all the necessary fittings for trying the system in a portion of the building. Is not this the first time that a gas company has been driven to offer to do work for nothing?"

CORRUPTION OF CORPORATION OFFICIALS.—Lord Randolph Churchill has given notice of the following important new clauses to the Local Government Bill:—(1) Every person who, being a member, officer, or servant of any corporation, council, board, commission, or other public body whose expenses are wholly or in part defrayed out of local taxes, rates, or assessments, shall, by himself, or by or in conjunction with any other person, corruptly promise, solicit, pay, receive, or agree to pay or receive, by or for himself, or by or for any other person, any gift, loan, fee, reward, advantage, or gratification whatever in respect of any contract work, purchase or sale of land or property, or any other matter or transaction, or proposed transaction whatsoever in which the public body of which he is a member, officer, or servant is concerned shall be guilty of a misdemeanour. (2) Any member, officer, or servant of any board or other public body as aforesaid shall on trial and conviction for a misdemeanour under this Act be liable, at the discretion of the Court before which he is convicted, to be imprisoned for any period not exceeding two years, with or without hard labour, or to any fine not exceeding £500; and shall be incapable of being elected to serve upon (and if elected his election shall be void) any board or other public body for seven years from the date of his conviction, and in the event of a second conviction for a like offence he shall, in addition to the foregoing penalties, be forever incapable of serving upon any such board or other public body, and his name shall be struck off the list of persons entitled to vote at a parliamentary or any other election; and any such officer or servant in the employ of any such board or public body by the fact of such conviction shall forfeit his right and claim to any compensation or pension to which he would otherwise become entitled."

GAS LIQUOR WORKS AND THE ALKALI ACT.

In the JOURNAL of the 3rd inst., we dealt generally with the recently-issued twenty-fourth annual report of the Chief Inspector under the Alkali, &c., Works Regulation Act (Mr. A. E. Fletcher), and gave some extracts from the reports presented by the District Inspectors associated with him. We now complete our notice by reproducing those portions of the remaining reports in which our readers are most interested.

In the South Midland District (No. 5), which is under the control of Mr. E. Jackson, F.C.S., there were 4 gas liquor or liquid ammonia, and 57 sulphate of ammonia processes under inspection last year. Two works in which sulphate was manufactured ceased to register; but, on the other hand, three new ones, and one dealing with gas liquor, were put upon the books. The method of dealing with the noxious gases are as follows:—In 43 works they are arrested in oxide of iron; in five, they are burned in oil of vitriol chambers; in three, they are passed into the hydraulic main; and in two the Claus process, with final scrubber and purifier, is adopted. No. sulphuretted hydrogen was evolved in two works; and the remaining two were idle. At one of the five works mentioned, where burning and passing into the vitriol chambers is the recognized method of dealing with the sulphuretted hydrogen, considerable trouble was experienced in maintaining some portions of the apparatus in repair, when this method was resorted to. Difficulties of an unusual character were met with; and it has resulted in resorting temporarily to burning the sulphuretted hydrogen, and sending the sulphurous acid into the chimney, pending a more effectual method of treatment which is now under consideration. This is the only work in the district where one of the methods above referred to is not now used. At eight works additional oxide of iron purifiers were added during the year, to ensure greater safety in working. We learn that caking of the oxide of iron on the girds has become less frequent, owing to more effectual condensing space at works where it was deficient. The extension of the use of coke scrubbers for drying the gases before entering the purifier still continues; they are employed at nine works in the district for this purpose. The yield of sulphate of ammonia per ton of coal carbonized in the best works, and where coal is moderately rich in nitrogen, is 30 lbs., and even 31 lbs. have been obtained. The general adoption of one of the methods above described for arresting the sulphuretted hydrogen given off in the manufacture of sulphate of ammonia has resulted in a considerable reduction of sulphur acids escaping into the atmosphere throughout the district. When this class of works were first brought under protection, it was found that there were only seven cases in this district where any provision was made for dealing with the foul gases other than the combustion method—i.e., burning the sulphuretted hydrogen, and sending the resulting sulphurous acid into the atmosphere (or, still worse, permitting the sulphuretted hydrogen to escape unburnt). It may prove interesting to put into figures the saving thus effected by arresting the sulphur compounds generated over burning and sending into the atmosphere, as showing the beneficial operation of the Act. The gas water in this district may be taken as containing 0.50 per cent. available sulphur. In some instances it is as low as 0.25 per cent.; while 0.80 per cent. has also been found. Through the kindness of the managers, I am able to state that, taking the average of six typical works, 2500 gallons of gas water have been required to produce a ton of sulphate of ammonia. The total sulphur acids now arrested are equivalent to 2070 tons of sulphuric anhydride, or 828 tons of sulphur—a figure equal to the recoverable sulphur from vat waste in a moderate-sized alkali works. This to the sulphuric acid and sulphate of ammonia manufacture is equal to 2526 tons of oil of vitriol; and from the sulphate of ammonia produced in the district, gives a saving of 24 per cent. of the sulphur required to produce the oil of vitriol used, taking 15 owt. of oil of vitriol per ton of sulphate of ammonia. I may remark that there is one work in the district where it is claimed that from 20 to 25 per cent. of the sulphuric acid required for the sulphate of ammonia works is obtained from this source. In other works, where the sulphuretted hydrogen is burnt and sent into the oil of vitriol chambers, the quantity of sulphur from other sources—such as coal pyrites, spent oxide, &c.—is not accurately known, so that the distinct saving cannot be ascertained. As regards the total oil of vitriol thus recovered, it may not appear to be a large figure, considering the area over which the works representing the total are spread. I give, however, three works, showing the amount of oil of vitriol kept out of the atmosphere in the vicinity of the works in each particular case in a year (such works are usually only in operation from six to nine months of the year, so that the quantities given below would be spread over a shorter time):—(1) Large work, situated in an important residential suburb of a large town; 211 tons of oil of vitriol kept out of the atmosphere per annum by adopting a method for arresting sulphuretted hydrogen. (2) Large work, situated in an agricultural and manufacturing district; 259 tons do. (3) Large work, situated in a populous portion of the town; 616 tons do. Feldmann stills are now in operation at four works in the district, and others are in course of erection. One work (No. 1542) is selected by Mr. Jackson for special mention. The manager has erected a Simons or Grüneberg still. The gas liquor is pumped up into a tank large enough to hold a 24 hours' supply, from which it gravitates to the still, passing on its way through a superheater, whereby the waste heat from the saturator is utilized, and delivering the water into the still at about 180° Fahr. The saturator is of a usual pattern. The foul gases are made to pass through a series of iron pipes air-cooled; and the sulphuretted hydrogen and carbonic acid enter a Claus kiln, and pass on into the chamber, where the sulphur is deposited. The residual gases, on leaving the chamber, go into a vertical scrubber packed with limestone kept moist with water, where any sulphuretted acid is taken up, and thence into an open oxide of iron purifier to arrest any sulphuretted hydrogen. The rate of make is equal to 1 ton of sulphate of ammonia per day. The air is carefully measured. The sulphur-kiln has not yet been emptied. The acidity of the exit gases, when examined, has been found 1.10 grains of total acids as sulphur trioxide per cubic foot; but sulphuretted hydrogen is always present in distinct quantity. At another works, where the Claus method is also in operation as far as the ultimate result is concerned—preventing the escape of noxious gases—the apparatus has been quite a success; but as regards the Claus process proper, the gases entering the scrubber and leaving the chamber have possessed very variable and high acidities. The experience of the previous year was confirmed—both sulphuretted hydrogen and sulphurous acid escaping together. As to the general condition of the sulphate of ammonia apparatus, it has been maintained in very fine order. At another works, the Claus apparatus has only been in work for a short period, and the plant is now undergoing considerable alteration. So far it appears better to work this process with a trace of sulphurous acid at the exit, since with the admission of a slight excess of air sulphuretted hydrogen is almost always found; thus keeping the sulphuretted hydrogen in slight excess it is arrested in oxide of iron, whereas if sulphurous acid escapes it is absorbed in the alkaline scrubber, and so sulphur is lost. Mr. Jackson thinks that a little more experience with the peculiarities of the process may perhaps result in a more approved form of kiln, whereby the curious point of

sulphuretted hydrogen and sulphurous acid escaping together in considerable quantities may be prevented.

Coming to the south-west of England and South Wales (district No. 6), we find from Mr. Fryer's report that many improvements were carried out last year in the plant connected with the manufacture of sulphate of ammonia. Particulars are given of these alterations. There are 61 works registered where the manufacture of muriate and sulphate of ammonia is carried on; and these produced about 6500 tons of sulphate during the year. The average of the purifiers in this district shows that 82 cubic feet of oxide of iron, occupying 54 square feet of area, are employed per ton of sulphate made per week. A continuous system of distillation is in use at some of the works, while an intermittent system is employed in others. The manufacture of sulphate was commenced at two works which were previously under inspection for other processes; and two new works applied for certificates during the year. One of these is a small works where not more than 400 tons of coal are carbonized per annum; and sulphate plant was erected there by Mr. John J. Jervis, Manager of the New Swindon Gas Works. A coke scrubber is made use of instead of the enormous length of cooling and condensing pipes usually considered necessary. The purifier merely consists of a heap of oxide of iron; and the pipe conveying the sulphuretted hydrogen is brought through the centre of the heap downwards, terminating in four radiating channels made by loose bricks covered with an ordinary purifier grid. This form of purifier, Mr. Fryer says, is not only simple and inexpensive, but performs its work effectively.*

Owing to the ill-health of Mr. Brereton Todd, the Inspector for district No. 7 (the south-east of England), he was temporarily relieved of a portion of his duties; the north-eastern counties being given to Mr. F. N. Sutton, F.I.C., F.C.S., an Assistant of the Chief Inspector. In the district reported upon by Mr. Todd, there were last year 31 sulphate of ammonia works registered, in which 4219 tons of salt were made. The sulphuretted hydrogen which had to be dealt with in these works had previously been so mixed with vapour that there was some difficulty in getting it dry enough for decomposing. The coke column recommended in the previous report for retaining or condensing this vapour has been so effectual, that Mr. Todd thinks it will soon be in general use. In many of the works it has already been adopted. He considers it is the greatest improvement made since the process came under inspection. There was only one complaint last year, which was investigated in August by the Chief Inspector. Although the owner did not believe that his works were the cause of it, Mr. Todd felt convinced it was the result of his men neglecting to keep sufficient fire during the night for burning the sulphuretted hydrogen. The owner has, therefore, now erected two large oxide purifiers. During the six years that sulphate of ammonia works have been under inspection, there have been only two complaints, both being about works in which the sulphuretted hydrogen was burnt instead of being decomposed in an oxide purifier. Particulars are given of the methods employed for testing the vapour and sulphuretted hydrogen generated during the manufacture of sulphate of ammonia.

In the portion of the district under Mr. Sutton's inspection, there are 33 sulphate of ammonia works, in which 29,906 tons of sulphate were produced last year. Many important improvements were effected in the plant; and the general condition of the works is reported as satisfactory, although alterations are required in several. Mr. Sutton confesses that he was not able to bestow very much attention on this class of works during the year, owing to want of time. But he gives the following particulars as to the works he visited. The Claus sulphur-recovery process was erected, and is now being used at one large works; but at present it is not altogether satisfactory as regards the means of absorbing the final gases escaping from the depositing chambers. It is a great improvement upon the former method employed in dealing with the foul gases; the output of sulphate being large, and the sulphuretted hydrogen having been formerly burnt in the boiler fire. Another large works has since June been experimenting in burning the sulphuretted hydrogen direct into the vitriol chambers, instead of absorbing it in oxide of iron, and then burning. The experiment has been so successful that lately the whole amount of sulphuretted hydrogen produced has been burnt into sulphurous acid, and converted into sulphuric acid direct; thus saving a considerable sum in the cost of labour. As the process has only been working for a few months, it cannot yet be definitely pronounced a permanent success. Another Claus plant is being erected at a gas-works which is about to commence the manufacture of sulphate of ammonia. At one works a new and improved kiln has been built for burning the sulphur gases from the saturator; the resulting sulphurous acid being made to raise steam by passing through the flues of an old Cornish boiler before entering the Glover tower on its way to the oil of vitriol chambers. The absorption of sulphuretted hydrogen in oxide of iron at some of the works is unsatisfactory, chiefly on account of insufficient cooling plant; the gas entering the oxide too hot, and saturated with moisture. Where coke scrubbers have been adopted, all such difficulties have been entirely removed. To give an example of the effect of coke in reducing the temperature and moisture of gases, at one works, where the cooling plant itself is somewhat small, an iron cylinder 30 feet high by 4 feet in diameter, filled with coke, was erected. This is unnecessarily high; it being an old disused piece of plant which was made use of for the purpose. The gases are hot on entering this, but perfectly cold and dry when leaving it. Each of the two purifiers is 9 feet by 4 feet by 6 feet deep, having a single bed of oxide 5 feet thick, which only requires changing once in six months; the make of sulphate for that time being 20 tons. No trace of caking or back pressure is noticeable; and the oxide is very rich in sulphur on removal. Many of the works still burn the foul gases from the saturators; but in five cases only can they be said to be thoroughly burnt. At two of these works, the resulting sulphurous acid passes to the vitriol chambers; at the other three, a special kiln is employed, having three flues one above another. The gas enters quite cold at the bottom with an excess of air, and burns continuously; a gas-jet being so placed that the sulphuretted hydrogen cannot fail to burn. The gas-jet is only a precaution which is rarely needed; for the fire-brick lining of the flue is always at a bright red heat, and no escaping sulphuretted hydrogen has ever been noticed. The average acidity of two of the chimneys connected with these flues is 1 grain and 1.15 grains as sulphur trioxide per cubic foot of the gases. In all other cases the system of burning the gases cannot be commended; and it is to be hoped many of these works will during next year adopt the method of arresting their sulphuretted hydrogen in oxide of iron.

It now only remains to deal briefly with the report on Scotland, where, as already stated, 65 processes relating to the manufacture of sulphate and muriate of ammonia were under inspection last year; 31,668 tons of sulphate being made. In regard to the gas-liquor works, Mr. W. S. Curphey (the co-Inspector with Dr. Blatherwick) stated that the use of the oxide of iron purifier is being extended; and in five works this method of dealing with the noxious gases was adopted during the year. The number of smaller works where burning of the gases is still con-

tinued is considerable. The average results of tests taken in these cases shows an acidity equivalent to 0.36 grain of sulphur trioxide per cubic foot. This is a low figure even for coal smoke, and is attributable in part to small escapes of ammonia, which in one instance was observed to entirely neutralize the acidity of the chimney gases. Continuous stills in the larger works are gradually displacing the older boiler-like form, in which each charge is worked off separately. In the former, the production of noxious gases is uniform throughout the operation—thus facilitating their destruction; in the latter, the production of noxious gases is very irregular—the chief portion being driven off in the early part of the distillation.

THE GAS AND CHEMICAL WORKS OF THE LEICESTER CORPORATION.

Last Thursday week, on the invitation of the Chairman of the Gas Committee of the Leicester Corporation (Alderman E. Wood), the members of the Town Council and a number of other gentlemen inspected the extensions now in progress at the Aylestone Road gas-works, and also the chemical-works, of the Corporation. The party were accompanied by the Gas Engineer (Mr. A. Colson, Assoc. M. Inst. C.E.). In connection with a notice of this visit, one of the local papers gave the following particulars as to the works:—

The determination to enlarge the Aylestone Road works, in order to place the Gas Committee in a position to meet the anticipated demand for gas, was come to by the Town Council, on the Committee's advice, in the early part of last year. In a report submitted by Mr. Colson, it was shown that the maximum daily consumption of gas had increased from 3,620,000 cubic feet in 1883 to 4,947,000 cubic feet in 1887, and that the existing works, both at Belgrave Gate and Aylestone Road, should not be relied upon to maintain the supply beyond the winter of 1889 and 1890. The Committee were authorized to erect at Aylestone Road, according to plans submitted by the Engineer, a second section of the works, which, when completed, will be capable of manufacturing and delivering an additional $\frac{1}{4}$ million cubic feet of gas per day. The estimated cost of the works is £150,000. But it is neither necessary, nor is it the intention of the Committee, to spend at present more than £100,000, as with this expenditure the works can be made capable of meeting the demand for gas for five or six years, after which the remaining £50,000 will be expended to complete the works as the consumption of gas increases. The works (with which good progress has been made) have been designed with the view to the utmost economy of labour in working. The whole of the retorts will be placed in one house—a stage house—measuring internally 368 feet long and 80 feet wide; and when finished it will be 43 feet from floor-line to roof. At present the building is only about 25 feet high; but Mr. Colson anticipates having it roofed in before Christmas. The house will contain 240 retorts, each 22 feet long, all of which will be heated by regenerator furnaces, and will be capable of carbonizing 400 tons of coal per day, equal to a make of about $\frac{1}{4}$ million cubic feet of gas. On either side of the retort-house are coal-stores, 50 feet wide, running the entire length of the house. The coal will be delivered direct into the stores by overhead railways, and deposited in front of the retorts through suitable openings in the division walls between the retort-house and coal-stores. In designing the retort-house, care has been taken to make it suitable for any kind of stoking machinery it may hereafter be advisable to adopt. In the spacious coke-yards on either side of the house, railway sidings have been laid down, and wagon-docks constructed for the convenience of loading coke opposite; and within a short distance of the retort-house will stand a fine block of buildings, consisting of boiler and engine rooms, fitting and carpenters' shops, smithy, foreman's office, workmen's wash-house, baths, and mess-room; also (with a separate entrance) a good reading-room. At present only the foundations of this block are in. Nothing, as yet, has been done towards the erection of either condensers, washers and scrubbers, engines and boilers, or purifying plant. The erection of the latter the Committee will defer as long as possible, in order to see the results of various experiments now being made in different parts of the country with the object of the more complete elimination of the sulphur compounds. Some of the experiments have proved so far successful that the Committee are sanguine of being able to supply gas from their new works, when completed, of far greater purity than has hitherto been done, either here or elsewhere, and this by processes that will not create any nuisance whatever. Two gasholder tanks are practically finished. They are 200 feet in diameter and 38 feet deep, and are built of brick and stone, concrete and puddle. The holders will each contain 2 $\frac{1}{2}$ million cubic feet of gas. The Committee expect to have the works ready for making gas in the early part of the year 1890; but one holder will be completed by next summer. The total productive capacity of the Aylestone Road works when the present extensions are completed will be a little over 7 million cubic feet per day.

The chemical-works, the erection of which was commenced in 1885, were completed last year. They are placed at the back of the gas-works, at the extreme end of the land belonging to the Gas Committee, and abut upon the River Soar. The object of so placing them was not only to secure good river frontage, but also to locate the works as far as possible from all dwellings. Here the ammoniacal liquor is worked up into sulphate of ammonia and sulphur; while the tar, crude naphtha, heavy naphtha, light oil, carbolic acid, creosote, green oil, anthracene, naphthalene, and pitch are produced. The best modern appliances have been provided, and the most approved methods are adopted in the manufacture of these products; and so carefully are the various operations carried on that practically no nuisance whatever arises therefrom. In the centre of the works is a small plot of ground, cultivated, with the object of ascertaining whether anything is given off in the manufacturing processes in any way detrimental to vegetation. Here are to be seen growing in as healthy and flourishing a condition as in any country garden a variety of flowers and vegetables. The total cost of the works was a little less than £20,000, which sum included the widening of the River Soar and the construction of wharves and a railway siding. The works have been visited by many deputations from all parts of the country, and are considered to be quite model works and second to none. The chemical manufactory at the old works at Belgrave Gate has, since the opening of the new one, been entirely abandoned and dismantled.

After the inspection, the party took luncheon in a marquee erected on a field adjoining the chemical works. Alderman Wood presided, and, in responding to the toast of "The Health of the Chairman and Members of the Gas Committee," said the consumption of gas in the borough during last year was a little more than 900 million cubic feet, and their present rate of progress would bring them up to nearly 1000 millions this year; so that the Gas Committee were not behind in their duty when they recommended the extension of the works they had seen that day. The progress of the gas-works had been a fortunate thing for the borough. Since the Corporation had acquired the works, the price of the gas had been reduced from 2s. 10d. in the borough and 3s. 4d. in the outlying districts, to 2s. 4d. in the borough and 2s. 8d. outside; and this meant an annual reduction of £18,000 to the customers of gas. In addition to this, although they gave £250,000 premium for the works, they had contributed £150,000

* The apparatus here referred to was described by Mr. Jervis at the meeting of the South-West Association in March last (see JOURNAL, Vol. LI., p. 553).

in a period of 2½ years to the reduction of the rates, had accumulated a reserve and renewal fund amounting to nearly £20,000, and paid off £35,000 of the capital. He asked those present to judge whether the character and stability of the works had not been fully maintained while this was being done. Nor had it been effected at the expense of the men employed by the Gas Department. The wages of the men in 1881 were 16s. a week; last year they averaged 29s. a week, independent of the officials. So that fair attention was paid to the remuneration of those who "bore the burden and heat of the day." Alderman Wood then referred to the change in the management which took place a few years ago. He was gratified to say that not a single member of the Committee, so far as he knew, had any cause to regret the appointment of their present Engineer. Mr. Colson had devoted himself as far as possible to labour-saving appliances; and by one alteration alone saved his salary twice over every year. He paid special attention to the chemical works, and prepared plans and recommended them to the Committee. They were adopted and carried out without a single penny for "extras," or a single accident; and the present extension of the works, involving an outlay of something like £150,000, was being done entirely under the superintendence of their Engineer. He thought they would feel, therefore, that the greatest possible credit was due to Mr. Colson. He was there early and late; and the credit of the success of the department was largely due to the industry and ability of their Engineer.

ARBROATH GAS CORPORATION.

THE PAST YEAR'S WORKING.—PROPOSED EXTENSION OF THE WORKS.

The Annual Meeting of the Arbroath Gas Corporation was held last Thursday—Provost Anderson in the chair. The accounts for the year ending the 31st of May last, with the Auditor's report thereon, were submitted. From the abstract of the accounts it appeared that the revenue from gas during the year was £8341 15s. 2d.; from gas meters, £281 5s. 10d.; tar sold, £362 2s. 9d.; cinders sold, £49 9s. 3d. Except on meters, there was an increase on all these items. On the year's working there was a surplus of £180 2s. 2d., as against a surplus of £41 18s. 6d. last year.

Mr. CARGILL, Convener of the Finance Committee, said the accounts showed a saving during the year on materials of £44 17s. 3d., on the retort account of £59 4s. 3d., and on the meter account of £24 19s. 2d. In the pipe account there was an increase of £30 14s. 2d., explainable by additional mains having been laid down in new streets and renewals. Salaries and wages showed an increase of £71 12s. 8d. The explanation given of this by the Manager (Mr. R. S. Carlow) was that had there been more work done in connection with the retorts, and the wages paid for this work should have been debited to the retort account, instead of to the general wages account. On rates and taxes there was an increase of £23 9s. 1d. The interest account had decreased £12 10s. 9d., owing to certain annuities having been paid off. A sum of £200 had been charged for repairs during the year; £85 2s. 11d. had been credited to the account for consumers' share of profits; and there was in addition £64 3s. 7d. of previous balances at the credit of that account. The total revenue for the year was £8623 1s.; being an increase of £406 15s. 5d. on the previous year. This large increase was accounted for by there having been no rebate allowed, and also by there having been paid close on £200 for the increased quantity of gas consumed in the street lamps. Mr. Carlow's estimate for the latter had proved to be correct. The result of the whole transactions was a credit balance of £180 2s. 2d., one-half of which went to the Town Council for public improvements, and the other half to the credit of the Gas Commission and to the consumers by way of rebate. The property account had increased by £172 3s. 5d., and now stood at £10,817 6s. 9d. Upon the whole, he considered the year's account very satisfactory. Turning to the estimates for next year, he found that they showed a credit balance in favour of the Corporation of £225, which would have been increased by £200 had they not deemed it advisable to credit the sinking fund with £400 instead of £200, in view of the surplus anticipated for the current year, and the largely increased expenditure on the proposed extension of the works. The estimates were less upon the whole, especially on the items of coal and lime; the saving on which alone would be about £300. In conclusion, he formally moved the approval of the report.

Baillie KEITH seconded the motion, and it was adopted.

The estimates for the ensuing year were approved of; and, on the recommendation of the Committee of Management, it was agreed to fix the price of gas at 4s. 3d. per 1000 cubic feet (being the same as last year), and to allow a rebate of 1d. per 1000 cubic feet to consumers, which would leave a balance of £11 12s. 8d. at the credit of this account.

The CLERK (Mr. D. Chapel) read the report of Mr. R. Mitchell, Engineer of the Edinburgh Gas Company, who had been requested by the Corporation to inspect the works, and give his views on the report of the Sub-Committee respecting the proposed extension of the works at a cost of about £7000. Mr. Mitchell stated that he had visited Arbroath on three occasions, and had very carefully examined the gas-works and adjoining property of the Commission, and was in a position to consider fully the recommendations of the Sub-Committee for rendering the works more efficient; thereby increasing the productive power, so as to meet the requirements of the town for a considerable number of years. In taking up the report, he would for convenience sake follow the whole question in the order dealt with by the Sub-Committee. First as the erection of new works. Had the present works of the Commission been in a dilapidated condition, whereby a large outlay for renewal would have been required in a few years he would have recommended, without hesitation, that such expenditure should be laid out upon a new site; and no piece of ground was better adapted than the town land or that adjoining, where a connection with the railway could be easily formed, thereby saving all cartages, and having additional advantages in disposing of the refuse. The residual products, too, could either be sent off by rail, or manufactured on the spot. A better supply of gas to the low-lying part of the town could also be satisfactorily secured with a smaller initial pressure at the works. Notwithstanding all these advantages, however, it did not appear to him that such an expenditure at the present time would be either judicious or prudent, owing to the high state of efficiency of the present works. Next as to regenerative furnaces. He considered that for works like those of the Arbroath Corporation, the setting of eight retorts recommended by the Sub-Committee would be quite unsuitable. No matter what overlapping, with smaller settings, might be made, they could not possibly work the setting in the same continuous manner as could be done with a setting of five retorts. As to additional storage, he agreed with the recommendation of the Committee that a new gasholder and tank should be constructed on the vacant piece of ground adjoining the present large holder, and that provision should be made in its construction for its being telescoped at any future time if found necessary. He also agreed with the Committee as to the desirability of having additional purifying space. Not only were the present purifiers in a dilapidated condition, but they presented too small an area for the quantity of gas requiring to be passed. He considered the estimate of saving given by the Manager in the event of new purifiers being erected very moderate indeed, and should be inclined

to say that the saving would not be less than £100 per annum. He agreed with the Manager and the Sub-Committee in their proposal to lay an independent main direct from the works to the lowest parts of the town; and recommended that it should be proceeded with at the earliest convenience of the Commission. In conclusion, Mr. Mitchell stated that the arrangements made by the Commission for financing the cost of the extensions were to his mind thoroughly satisfactory. The Committee of Management recommended (with one dissentient) that the Corporation should adopt the Sub-Committee's report as qualified by Mr. Mitchell's report, with the exception that the suggestion of the latter in regard to the setting of the retorts be not adopted; and that, as recommended by the Sub-Committee, eight retorts should be put in one oven, and that the final decision as to the proposed extension of the works should be deferred one month to allow of further consideration of the matter. After some conversation, the Committee's recommendation was adopted.

THE ROCHDALE GAS COMMITTEE AND THEIR GAS MANAGER.

MR. BRAY'S CHARGES AGAINST THE COUNCIL OF THE GAS INSTITUTE.

At the last Meeting of the Rochdale Town Council—the Mayor (Mr. J. E. Petrie) presiding—the Gas Committee presented the following resolution:—"The Committee, having listened to Mr. Ball's explanation of his connection with The Gas Institute, and of his share in the doings of the Council of that Institute with regard to the matters published by Mr. George Bray in pamphlet form, and distributed to members of this Corporation, resolved that the Committee are perfectly satisfied with the explanation of Mr. Ball."

Alderman PETRIE, in answer to a request for further information, explained the origin of the difference between Mr. Bray and the Council of The Gas Institute, and pointed out that it was four years after the Crystal Palace Exhibition when Mr. Ball was elected a member of the Council. All he had had to do in the matter was voting against Mr. Bray's proposal to appoint a Committee of investigation. It was a matter of opinion on Mr. Ball's part; and the Committee could not find fault with him in voting according to his judgment. At any rate, they saw no connection between anything he had done there and his work as the Manager of the Rochdale Gas-Works; and, having this view of it, the Committee were perfectly unanimous in saying that Mr. Ball's explanation was satisfactory.

Mr. SHARP asked if the Corporation subscribed anything to the Crystal Palace Exhibition.

Mr. HANDLEY: Do the Committee intend to ask Mr. Ball to withdraw from the Institute?

Alderman PETRIE: He is no longer on the Council. Mr. Handley wishes to know if we asked, or did we think of asking, Mr. Ball to retire from the Institute on account of what he has done. [Mr. TOPPER: Or what other people have done.] Certainly not. As to Mr. Sharp's question, I am not aware that we subscribed a shilling to the exhibition.

Mr. HANDLEY said he had carefully read through Mr. Bray's pamphlet; and as that had now become public property, the Council ought to make some inquiry as to the truth of the allegations therein made. He thought very highly of Mr. Ball as a Gas Manager; and he believed that Mr. Ball would see it to his credit and advantage in every way to withdraw from the management of the Institute.

Mr. WATSON did not think the Council had anything to do with the personal dispute between Mr. Bray and any members of The Gas Institute. He objected to the Council entering into the matter, considering that Mr. Ball did not go on the Council till four years after the exhibition, and that he was not now connected with the management of the Institute in any way.

Mr. W. LORD said he was not completely satisfied with the report of the Committee's investigation. He did not consider the Council should enter into the matter of the dispute between Mr. Bray and the members of The Gas Institute; but he certainly thought there was room for further explanation as to the position which Mr. Ball occupied in relation to the Institute. He thought the Committee might perhaps investigate a little further, and place the ratepayers in a better position to judge of the matter.

Mr. KERSHAW remarked that they could only inquire into the matter by hearing both sides; and this would mean great expense. Even if they did that, he thought they would get no nearer in the end. He did not think Mr. Ball was to blame for anything he had done.

Alderman LITTLEWOOD said that at the last meeting of the Council he voted against the proposed increase in Mr. Ball's salary, not because he objected to it *per se*, but on the broad ground that it was inadvisable to increase the salary of any public servant who was under the shadow of, it might be, a distant imputation. He was sorry the explanation now given could not be furnished at the last meeting, as he could then have supported the proposal to increase Mr. Ball's salary. As the Chairman of the Gas Committee had said, the Council had nothing to do with the dispute between Mr. Bray and the members of The Gas Institute, against whom he made certain charges. All they were concerned with, as members of the Council, was Mr. Ball. It appeared that his transactions had simply been that, on the Council, he voted with those gentlemen as to whose conduct Mr. Bray wanted an inquiry. He thought it was quite probable any of them would have done the same. The only other connection with Mr. Ball in the pamphlet was that Mr. Bray levelled general charges of venality and corruption against certain people. He did not know that Mr. Ball was in any shape or form connected with those charges.—Mr. Bray specified no one as to them; and it would be very unfair to go to a public servant and say, "Here are some general charges; I don't know whether they apply to you or not, but you must prove yourself innocent." A man would have no hold on his character if charges could be brought in that way. If specific charges of corruption were made against Mr. Ball, the Council could look into the matter; but at present Mr. Ball could only ask to prove himself innocent of something which was not charged against him.

Alderman MILNE said that, after hearing Mr. Ball's statement, he felt so satisfied that he at once moved that the explanation was satisfactory to the Committee. He was quite sure that any member of the Council would have taken the same view of the matter if he had been at the Committee meeting.

Mr. T. CHEETHAM said that, having been a member of the Gas Committee for several years, he had come much in contact with Mr. Ball; and whenever Mr. Bray's name had been mentioned, he never remembered Mr. Ball saying a word derogatory to his character or in depreciation of his burners. Even Mr. Bray made some "honourable exceptions" in levelling his charges; and he (Mr. Cheetham) thought Mr. Ball was more sinned against than sinning.

Mr. ROBINSON said he believed Mr. Ball to be an honest man; and another opinion he had formed was that Mr. Bray was a disappointed man, and was making indiscriminate charges.

The Mayor said he had received a letter from Mr. George Bray in reference to the remarks he had made about that gentleman's pamphlet

at the last meeting. He then said that the pamphlets had been sent out at an unfortunate time, and that perhaps it had been done intentionally, as they had come to every member of the Council on the night before the decision as to Mr. Ball's salary. He took this view of it; and many others did the same. Mr. Bray stated in his letter that this was not so. He (the Mayor) unhesitatingly expressed his regret that he had put a construction on the matter which Mr. Bray said was not a correct one. The Gas Committee's minutes were then passed.

RECENT SALES OF SHARES.

On Tuesday last, Messrs. Edwin Fox and Bousfield sold at the Auction Mart, Tokenhouse Yard, about one quarter of a King's share and also 20 £100 new fully paid-up shares in the *New River Company*. The first 13 lots each comprised the 96th part of a King's share; the prices realized being: Three lots, £930 each; one, £925; four, £920; two, £915; and three, £910. The next 16 lots each consisted of the 130th part of a King's share, and produced: Two, £700; two, £680; one, £675; one, £660; eight, £650; and two, £640. The 20 £100 new shares, the last dividend on which was at the rate of £12 2s. 6d. per annum, were sold as follows:—Three at £355; three at £354; one at £353; three at £352; and ten at £350. The total amount produced by the portion of the King's share was £22,530; and by the new shares, £7036—making together £29,566. As will be seen by the above figures, the 96th parts of a King's share fetched fairly uniform prices, although the bidding for them was very inert. The succeeding lots—the 130th parts of a share—experienced a serious drop from £700 to £640; while the offers for the new shares were brisk and even.

Messrs. Blake, Haddock, and Carpenter, of Croydon, disposed, on Thursday, of 15 fully paid-up shares in the *Mitcham and Wimbledon Gas Company*, on which 10 per cent. dividends had been paid, at £20 5s. per share, and of 7 similar shares at £21 each.

At the Royal Hotel, West Hartlepool, last Wednesday, a number of shares in the *Hartlepool Gas and Water Company* were sold by public auction by Mr. Hunter. There was a numerous attendance, which included the Chairman and several Directors of the Company, and the bidding was spirited. There were 61 shares, each of £5 value, in the "A," "B" and "C" classes, and these sold for prices ranging from £7 10s. to £7 13s. apiece; and 47 £10 shares in the "D" old and "D" new classes. In these classes, the paid-up shares sold for £14 11s., £14 12s., and £14 13s. 6d. each; whilst those on which £9 only had been paid went for £13 14s.

THE ELECTRIC LIGHTING EXPERIMENT AT LEAMINGTON.

At the Meeting of the Leamington Town Council on Monday last week, the Watch Committee reported that the Midland Electric Light and Power Company had applied for permission to erect four arc lamps on the Town Hall; and recommended that the same be granted, on condition that the lights were placed at a distance of not more than 30 feet from the ground. In moving the adoption of the report, Alderman Wackrill explained that in the first instance the wish of the Company was to place these lights in the clock tower, at an altitude of 100 feet. Dr. Eardley Wilnot inquired if the application of the Company to introduce the arc light was not practically an admission on their part that the incandescent light now in use was a failure; also, if it was not a fact that the latter lamps were becoming worse every day, and what steps were being taken to bring the light up to the requisite standard. Alderman Wackrill denied that the application of the Company in any way implied that the present lighting was a failure. With regard to the experiments in connection with the electric lighting scheme, he said they would be continued as long as they were found to serve a useful purpose. Mr. Crowther Davies pronounced the incandescent light a miserable failure, and said the state of things which led him two months ago to move that notice be given to the Company to terminate the contract had been aggravated. He thought the Company had failed to light the town in a satisfactory manner. If they granted the Company permission to place on the Town Hall four arc lights each of 2000-candle power, the brilliancy of these lights would make the incandescent lights in the streets look like farthing rushlights. He held that the Council ought not to continue paying £400 a year for the present unsatisfactory system of lighting the Parade. Mr. Bright said that, though the incandescent light had not been sufficient for street purposes, it was an admirable illuminant indoors. He was in favour of the introduction of the arc light, as it would be one way of overcoming the failures of the past. Mr. Barter White feared that an attempt to light the Parade with the arc light would neither be economical nor satisfactory. After further discussion, the voting was taken, and the report adopted by a majority of one.

METROPOLIS WATER SUPPLY.

According to the returns furnished to the Registrar-General by the London Water Companies, the average quantity of water supplied daily to the Metropolis in the past month was 175,570,123 gallons, as against 179,578,401 gallons in the corresponding month of 1887. The number of houses served last month was 739,252, or at the rate of 237 gallons per house, and 30·4 gallons per head of the population. In June, 1887, the number of houses was 726,193; and the quantity of water allowed for each person, 31·7 gallons. Of the entire bulk of water supplied last month, 87,971,114 gallons were drawn from the Thames, and 87,599,009 gallons from the Lea and other sources.

Dr. E. Frankland, in the course of his report to the Registrar-General on the quality of the Metropolitan Water Supply last month, makes the following remarks:—"The Thames water sent out by the Chelsea, West Middlesex, Southwark, Grand Junction, and Lambeth Companies again exhibited a further reduction in the proportion of contained organic matter, which was unusually small in all the samples examined. All the samples were clear and bright. Of the water principally drawn from the Lea, that distributed by the New River Company contained less, and that by the East London Company slightly more, organic matter than the Thames supplies. Both samples were clear and bright. The deep-well water pumped by the Kent Company and by the Tottenham Local Board of Health contained, as usual, only a very small proportion of organic matter; while in the sample of the Colne Valley Company's supply, the organic matter was distinctly in excess of the average for this water."

INCREASED STOREAGE FOR CLITHEROE.—The Clitheroe Town Council have accepted a tender of Messrs. Ashmore, Benson, Pease, and Co., Limited, for the erection of a two-lift telescopic gasholder, at a cost of £1714.

REDUCTIONS IN PRICE.—The Directors of the *Isle of Thanet Gas Company* have given notice that, as from the 30th ult., the price of gas to private consumers will be reduced from 3s. 3d. to 3s. 1d. per 1000 cubic feet, also the charge for meters; and every facility will be afforded to those who are desirous of consuming gas, whether for lighting, cooking, or heating purposes.—At their meeting last Thursday, the *Heywood Town Council* decided to reduce the price of gas from 4s. 2d. to 4s. per 1000 cubic feet, with the present discounts.

TARAPACA WATER-WORKS COMPANY, LIMITED.

The Statutory Meeting of this Company was held last Tuesday, at the Cannon Street Hotel, E.C.—Mr. R. HARVEY in the chair.

The notice convening the meeting having been read, The CHAIRMAN said that, as the shareholders knew, the meeting was held in order to carry out the requirements of the Limited Liability Companies Act. Of course, they would scarcely expect that much progress had been made up to the present time. However, they had a report from the Engineer (Mr. W. R. Copland) which would be read, so that they might form an idea as to how far the works had progressed. He might mention that they had received a cablegram from Iquique, which told them how the Arica and Provedora water business was working which they took over from Colonel North, and on which the shareholders were promised in the prospectus 6 per cent. interest. He (the Chairman) was pleased to say that the amount received for the profits on that business was more than sufficient to pay the 6 per cent. interest, and that at the end of the six months they would have their dividend warrants sent out. The shareholders would also be glad to know that the staff, which sailed in the *Gulf of Trinidad*, had arrived safely at a port on the coast.

The Engineer's report on the progress of the works, to which the Chairman referred, was then read. It stated that the progress up to the present consisted principally in the manufacture and shipment of the materials required in the construction of the works. About 60,000 cast-iron pipes, which would extend to more than 100 miles, were required to complete the main conduit to Iquique and the various branches. Of this quantity, 16,760 pipes, or 28 per cent. of the total, had been shipped to Iquique; besides which some 3000 pipes were at present in course of shipment, or rather lying ready at the foundry. In addition to the above, there had been shipped about 50 per cent. of the lead and rope yarn required for jointing the pipes; 200 tons of Portland cement for foundations of water-tanks; about 21 tons of galvanized sheet iron; and the tools and appliances required in carrying out the works. The whole of the sluice-valves had been made and tested, and now await shipment. The construction of the 15 large malleable iron tanks for the storage of water at Iquique and at various points on the line of piping was proceeding rapidly; and three 50-foot diameter tanks would shortly be ready for shipment, while a number of the others were well advanced. The report concluded by stating that the Resident Engineer (Mr. Tuckwell) sailed from Liverpool on May 12, and was reported at Coronel on the 25th ult. It was therefore probable that by this time he would be in a position to get the works commenced.

The CHAIRMAN observed that the pipes sent out were sufficient for 28½ miles; and the diameters were 9, 7, 6, 5, 4, and 3 inches. There were 13 miles of 9-inch main. At the rate they were going on at present, the Engineer said that the whole of the pipes would be shipped within the six months from the commencement of the work—that was, three months from now. He (the Chairman) thought that within the 1½ years the Tarapaca Water-Works would be in full working order. The promise in the contract was two years.

No question being put by the shareholders, the Chairman declared the meeting closed.

NOTES FROM SCOTLAND.

(FROM OUR EDINBURGH CORRESPONDENT.)

EDINBURGH, *Saturday*.

The excellent results of the past year's working of the Edinburgh and Leith Gas Company have been partly discounted by the announcement, in connection with the transfer negotiations, that the profits of the Company were "about £27,000." As the report of the Directors in another column will show, this amount has not been quite reached; but the figure brought out—£26,313 16s. 1d.—is a magnificent rise from the sum of £18,491 which was reported a year ago. Without desiring to institute invidious comparisons, I may point out that the increase in one year of £7822 upon a make of 400 million cubic feet compares very favourably with the increase of nearly £13,000 which was reported the other day as having been made by the Edinburgh Company, whose output is taken at 800 millions. To be in the same ratio, the increase of profits in the Edinburgh Company ought to have been over £15,000. There are, of course, considerations that do not appear on the surface, which may disturb these calculations; but, taken as announced to the public, the above reflections lie on the surface. The great reduction in the cost of production which is referred to in Mr. Linton's report to the Directors is the most convincing testimony to the advantage which is to be derived from the employment of modern appliances. This report of Mr. Linton's should not be lost sight of by the civic authorities in the meantime, because it demonstrates what they may be able to do when they get the gas supply into their own hands, and shows that, if they profit by the experience of the Leith Company, and produce the whole of their output in a similar manner, there will be, at once, an augmentation of their available profits to the amount of several thousand pounds yearly. The low percentage of unaccounted-for gas—7·63 per cent.—is also a noteworthy feature in the Company's business—being the best proof that the whole of the plant is in good order.

Judging by the proceedings before the House of Commons Committee on Tuesday, the Edinburgh Corporations' Bill is likely to have a swift passage through the Legislature. The Joint Committee of the Corporations will thereby come in in a canter; and, in the short-lived memory of the public, will thus be likely to get credit beyond what they are entitled to. The date of transfer is close at hand; and both Gas Companies are already setting their house in order before quitting it for ever. To them the recollection of the past, with its rich returns, must be exceedingly sweet. It is to be hoped that the shareholders will enjoy no less pleasure in the return which they will have from the Corporations; and that, on the other hand, the Corporations may be able to conduct the undertakings with as much success as the Companies have done. The arrangements for the transfer have not proceeded far yet; but up to the present everything has gone smoothly since the agreement with the Leith Company was come to.

At the meeting of the Bromley Ferry Gas Commissioners on Monday, it was reported that the revenue for the past year was £5116 17s. 11d., and the expenditure £4939 7s. 6d. In the previous year these sums were £5275 18s. 7d. and £4965 5s. 4d. respectively. There is thus a decrease of revenue to the amount of about £159. With reference to this, it should not be forgotten that a year ago the revenue from meter-rents was reported to have amounted to £238 7s. 6d., and that a reduction of the charge was then made, as the result of which the return from meters during the past year was only £58—a difference of £180 7s. 6d., which more than represents the loss of revenue. Taking into account that £47 more was realized for secondary products than was estimated for, the state of the revenue shows that the amount of gas consumed was not up to that of the previous year. Perhaps the least satisfactory portion of the annual statement is that which refers to the increase of leakage from 6·81 to 8·17 per cent. The Commissioners are reducing the cost of their works by large sums year by year. They seem to be in a cheeseparing mood just now, as is exemplified by their recent reduction of the Manager's salary. It might

be worth their while considering whether the sound financial position of the Commissioners may not be impaired by this policy if it be carried too far, and to remember that works well equipped and well conducted are essentials to obtaining successful financial results.

The Tayport Police Commissioners on Monday resolved to approach the Dundee Water Commissioners with a request for a supply of water at a rate equivalent to that in Dundee. The Commissioners had offered water at 5d. per 1000 gallons; but, following the advice of Chief Magistrate Young, the Commissioners thought it would be preferable that a rate should be levied. Mr. Young said he calculated that a rate of 1s. 4½d. per pound on a rental of £6235 would be sufficient. In Dundee it is 1s. 2d. per pound.

The annual meeting of the Kirkcaldy Gas Company was held yesterday. It was reported that during the past year 686 yards of mains were laid; so that the mains now extend to 28 miles 1105 yards. The manufacture of gas for the past year was, per station meter, 66,305,600 cubic feet, as compared with 63,169,200 cubic feet in the previous year; the increase being 3,136,400 cubic feet. The profit and loss account for the year showed a net profit of £3236 3s. 5d. Out of this it was resolved to pay a dividend of 7s. 6d. per share, equal to about £2755 5s., and to carry the balance of £479 18s. 5d. to the credit of the depreciation fund. The meeting adopted the Directors' recommendation that the price of gas for the current year should be continued at 2s. 4d. per 1000 cubic feet.

The accounts of the Elgin Gas Commissioners for the past year show the output of gas to have been 13,022,050 cubic feet, and the revenue from its sale £3808. Meter-rents produced £116 9s.; and stove-rents £24 7s. 7d.

The Alloa Burgh Commissioners last Monday received the annual statement by the Gas Committee from which it appeared that during the past year £250 were spent on renewals, chiefly of the retort-bench, and that of a debt of £26,200, a sum of £6550 had been repaid; reducing the debt to £19,650, as against £23,250 when the Commissioners took over the undertaking in 1877. During the year the output of gas was 2½ million cubic feet more than in the previous year, while the coal account was £79 less. The Commissioners recommended that the price of gas should be reduced from 3s. 9d. to 3s. 6d. per 1000 cubic feet, and that discounts ranging from 2½ per cent. for accounts from £20 to £35, to 7½ per cent. upon those above £100, should be allowed. There was some conversation over this proposal; several of the Commissioners thinking that the small as well as the large consumers should have the benefit of a discount. The scheme, it was explained, would reduce the revenue by £130 a year; and, if applied to all customers, would be equal to a reduction of 1½d. per 1000 cubic feet. The Commissioners' recommendation was adopted. It was stated that the charge for public lighting was to be reduced from 10s. to 14s. 11d. per lamp.

(FROM OUR GLASGOW CORRESPONDENT.)

GLASGOW, Saturday.

In his capacity of Secretary of the North British Association of Gas Managers, Mr. R. S. Carlow, of the Arbroath Gas-Works, has just issued a capital "hill of fare" for the twenty-seventh annual meeting of that body, which is to be held in Glasgow on Thursday and Friday, the 26th and 27th inst., under the presidency of Mr. David Terrace, who was for so many years the zealous and efficient Secretary of the Association. In addition to the President's address, which is expected to be of considerable interest, there are no fewer than seven papers set down to be read, all dealing with subjects of practical importance to those engaged in the gas industry. On the evening of Thursday, the members of the Association and members of other similar bodies (who are freely invited to attend this year's meeting), and lady friends will dine together in the "Royal Bungalow," at the exhibition. The lady friends, many of whom are expected to visit the exhibition during the day, will have every facility offered them for inspecting the gas heating and cooking arrangements in the Bishop's Castle Café kitchen, which has already been described at some length in the JOURNAL. On the following day (Friday), there will be a capital excursion to Loch Lomond and Loch Long. It is expected that Mr. G. R. Hislop will be elected to the presidency of the Association in succession to Mr. Terrace; and that the meeting next year will be held at Dunfermline—a place of great interest, and one which is now easily reached by railway from all quarters. The fact that it is near the Forth Bridge will also, doubtless, aid in fixing that place for the twenty-eighth annual meeting of the Association.

The annual report on the accounts of the Johnstone Gas Commission has been issued. It shows that for the year ending the 15th of May, the gross profits amounted to £2908 19s. 9d.; and the net profits, after payments in reduction of loans, &c., to £499 18s. 3d. The works are valued at £20,813—not including £939 10s. of outstanding debts. The loans on the works amount to £21,252 12s. 5d. During the year there was paid for coals the sum of £1274 15s. 5d.; and for lime, £14 12s. For salaries and wages, the payments were £752 17s. 10d.; and the interest paid was £914 9s. 4d. The year's total revenue from gas was £3908 4s. 7d., and that from secondary products, &c., £198 14s. 3d. At present the price of gas is 4s. 4½d. per 1000 cubic feet, which is expected to be continued during the current year.

The report recently submitted to the Kilmarnock Town Council by the Gas Committee shows that the profits on the past year's working of the gas undertaking amount to upwards of £3000; and in view of this favourable state of affairs, the Committee have unanimously recommended a reduction in the price of gas from 3s. 11½d. to 3s. 6½d. per 1000 cubic feet—that is to say, a reduction of 5d. per 1000 feet.

At a meeting of the Greenock Gas Trust Committee last Tuesday, there was submitted the annual statement of the income and expenditure in connection with the gas supply for the past year. The profits were shown to be £4300; and it was agreed to recommend that the price of gas be reduced from 3s. 9d. to 3s. 6d. per 1000 cubic feet. There is a proposal to hand over to the Police Board £3000 to help in reducing the general taxation, and to devote the remaining £1300 to the liquidation of capital charges of former years and also to the sinking fund. These various matters, however, have yet to come before a full meeting of the Gas Trust for final settlement.

It is expected that the surplus profits on the Paisley Corporation gas undertaking for the past year will admit of the price of gas being reduced to 3s. 9½d. per 1000 cubic feet, if not even lower.

A statutory meeting of the Kilmory Gas Commissioners was held last Monday, at which the Auditors' annual report was submitted. The past year's profits amount to about £300, from which there has to be deducted the sum of £140 to pay principal and interest on the loan; leaving a balance of about £160 of clear profit, which the Commissioners propose applying to the reduction of the debt incurred on the new works, over and above the amount which they have already borrowed. It is proposed to reduce the price of gas from 4s. 7d. to 4s. 2d. per 1000 cubic feet.

The Directors of the Carlisle Gas Company have agreed to reduce the price of gas from 4s. 2d. to 3s. 9d. per 1000 cubic feet.

The Bothwell and Uddingston Gas Company held their annual meeting on Monday. From the balance-sheet and Directors' report for the past

year, it was shown that the profits made by last year's working, after charging revenue with all repairs and depreciation, amounted to £1307 3s. 9d., which sum added to £655 19s. 6d. brought forward from the previous year's accounts gave a total on appropriated profits of £1742 7s. 5d. On the recommendation of the Directors, it was agreed to apply £900 in payment of a dividend at the rate of 10 per cent., leaving a balance of £842 7s. 5d. to be carried forward to next year. The quantity of gas sold during the year was 16,966,300 cubic feet; being an increase over that of the previous year of 550,400 cubic feet. Including the quantities consumed in the public lamps and at the gas-works, the total consumption was 17,726,300 feet, as against 17,115,900 feet in the preceding year. To supply this amount, there was manufactured 19,096,300 cubic feet; and the leakage and unaccounted-for gas only reached the very low total of 7.1 per cent. It has been found necessary to proceed with the erection of a new gasholder to meet the increasing consumption of gas. The price of gas has been reduced to 4s. per 1000 cubic feet.

The annual meeting of the Irvine Gas Company was held on Tuesday, when the annual statement of accounts was submitted. A dividend at the rate of 10 per cent. on the original shares was declared. The increase in the consumption of gas was reported to be 540,000 cubic feet; and the gas had an average illuminating power of 26.75 standard candles.

At the last meeting of the Port-Glasgow Town Council, a long statement was made by one of the members, regarding more alleged trickery in conducting the gas affairs of the town; and he submitted a proposal which did not even find a seconder. His statement dealt chiefly with the lighting of private streets by the municipal authorities. It was subsequently reported that contracts had been made for the supply of 2600 tons of gas coal, at an average price of 11s. 2d. per ton. On the recommendation of the Gas Committee, it was agreed to reduce the deposits on meters used by consumers and the annual hire for the same.

As is usual just before the annual Fair holidays, the Glasgow pig-iron market has been very lifeless this week. Scotch warrants fluctuated in price between 38s. to 38s. 1d. one month. The close yesterday was 38s. cash buyers. Very little business has been done in Scotch special brands; and prices have not changed during the week. Cleveland warrants have been selling at 31s. 10½d. per ton, and hematite iron at 42s. 10½d. to 42s.

The demand for coal of various kinds continues to be rather brisk; but there is no improvement to report in regard to prices. Main coal is being shipped at 5s. 6d. f.o.b. at Glasgow, and steam coal is realizing 7s. 3d. to 7s. 9d. at the coaling cranes.

CURRENT SALES OF GAS PRODUCTS.

LIVERPOOL, July 14.

Sulphate of Ammonia.—There is practically very little change in the market, though quotations have hardened all round. Somewhat better prices have been accorded by consumers; and the dealers were obliged to follow suit. The principal transactions this week are at £11 12s. 6d. f.o.b. Hull; and £11 10s. f.o.b. Leith and Liverpool. The inquiries for August and September are very large; but the orders are either limited too low to admit of business, or they are taken up by speculators, of whom some cannot resist running the risk of the market, notwithstanding the passiveness of producers, who seem in no hurry to dispose of their present small make, and will not sell "forward" in the conviction of realizing better values before long. A continuance of the present unsettled weather would greatly favour the consumption of sulphate; and in anticipation of an active demand, higher prices do not look so far off as they were generally reported to be. The parcels on the market continue to be limited; and they are generally readily bought up at sellers' prices when purchasers find that they will not succeed in making bargains.

LONDON, July 14.

Tar Products.—The market has a holiday character about it. Business done is extremely small; and most of the products are hanging fire. Benzol is nominally quoted higher; but no business of any moment is reported. Prices: Tar, 15s. to 20s. per ton. Benzol, 90 per cent., 2s. 7d. per gallon; 60 per cent., 2s. 4d. Toluol, 1s. 6d. per gallon. Solvent naphtha, 1s. 1½d. per gallon. Crude naphtha, 30 per cent., 1s. per gallon. Light oil, 3½d. per gallon. Creosote, 1½d. per gallon. Pitch, 13s. to 16s. per ton. Carbolic acid (crude), 3s. 5d. per gallon. Cresylic acid, 10d. per gallon. Tar salts, 15s. per ton. Anthracene, 30 per cent., "A" quality, 1s. 4d. per unit; "B" quality, 1s.

Ammonia Products.—Sulphate is distinctly dull, and buyers all round are offering lower prices. The ever-increasing make of this article is a weak feature; and there are many who think that the ensuing season will bring much lower prices. Prices: Sulphate of ammonia, £11 2s. 6d. to £11 5s. 6d. per ton, less discount. Gas liquor (5° Twaddell), 8s. per ton, with a rise or fall of 1s. 6d. per degree. Liquor ammonia, 2d. per lb. Carbonate of ammonia, 3½d. per lb. Muriate of ammonia, brown, £18 per ton; white, £28. Sal ammoniac, £30 per ton.

[From the *Chemical Trade Journal*, July 14.]

Sulphate of Ammonia.—Lower prices continue to be offered at all the ports; and the manufacturers do not see their way to refuse business at the reduced values. Last week the agent of The Gaslight and Coke Company reduced his price by half-a-crown without being able to secure orders; proving beyond a doubt that the stuff is not yet wanted. Beyond a few West Indian orders, there is no inquiry, and may not be for some weeks yet. Fortunately we are on the period of shortest production; so that there is not much fear of any inordinate quantity being put on the market this month. Hull value is stated at £11 6s. 3d., while Leith and London is put down at £11 8s. 9d.; but these prices are quite abnormal, and represent a value reduced by speculation rather than the intrinsic value of the article.

Tar Products.—Never was the tar products market in a more unsatisfactory state than it stands at the present moment. With high values for tar the products from it are certainly weaker than a few weeks ago, although every effort is made to induce a contrary opinion. Meanwhile Continental consumers will not come forward to purchase; and there is but one outlet. The fact is that since we predicted a fall in the value of benzol, the trade has been forced into another channel. The Continental consumer has not taken so much benzol as formerly; but he has taken aniline instead, which at 8½d. has suited him better than purchasing benzol. This was the only way in which the price could be kept up. All other tar products remain without material change. The pitch market is a little disturbed by the late report of higher prices than usual being obtained; and some are holding to their stocks for a rise, but we have already expressed the opinion that there is no hope in the immediate future for this article.

SEVERE GAS EXPLOSION IN PARIS.—An alarming explosion of gas occurred in Paris, on Monday evening last week, at a restaurant known as the Grand Café. The building, which is three storeys high, was shaken from top to bottom. Only a few customers were in the house at the time, and no one was killed; but about 15 persons were injured, several seriously. The damage done to property is estimated at upwards of 100,000 frs.

HAWICK GAS COMPANY.—The annual general meeting of this Company was held on Friday, the 6th inst.—Mr. T. Laidlaw in the chair. The report of the Directors, the principal portions of which were given in the JOURNAL on the 3rd inst. (p. 35), with an abstract of the accounts, was adopted. Mr. Laidlaw was re-elected Chairman; and after some complimentary remarks by him on the Manager (Mr. J. Smith) and the Secretary (Mr. G. Grier), these gentlemen were re-appointed.

IMPROVED VALUE OF TAR.—At the meeting of the Walsall Town Council on Monday last week, the Gas Committee recommended that a contract should be entered into with Messrs. Robinson Bros. for the sale to them of all the surplus tar made at the two gas-works of the Corporation during one year from the 1st of July inst. Mr. Russell (by whom, in conjunction with the Town Clerk, the fresh contract for the sale of the tar had been arranged) mentioned that a gain of £100 a year would result to the town from the new terms.

THE BRISTOL GAS COMPANY AND THE GAS-FITTERS.—It may be remembered that shortly after the announcement that the Bristol Gas Company would supply gas-stoves, &c., to the public, and would fix them, a large number of the gas-fitters of the city memorialized the Company on the subject, and represented that the new departure proposed might injure their trade. The Company, having duly considered the memorial, have replied that they are only following a course which other gas companies long ago adopted.

THE CADOGAN ELECTRIC LIGHT COMPANY, LIMITED.—This is an undertaking started "to supply electric light from a central station to Belgravia and the Cadogan estate," the capital being £45,000. Money says of it: "The capital is altogether too insignificant, and will very likely be squandered in futile experiments. It is difficult to see what practical result can be achieved. It is true that the district is one of the most aristocratic of London; but we have yet to learn that such a recommendation carries any guarantee for the financial success of a veritable fad."

ANNUAL EXCURSION OF THE DOVER GAS-WORKS EMPLOYEES.—Last Wednesday the annual excursion of the *employés* at the Dover Gas-Works took place—Hampton Court being the locality selected; and a thoroughly satisfactory day was spent. The Chairman of the Company (Mr. W. Mannering) expressed his pleasure at seeing the men enjoying themselves; and said he hoped that for many years to come he should have the pleasure of meeting them on similar occasions. He remarked that since the previous excursion Mr. R. Herring had established a benevolent fund and a reading-room at the works. These were useful additions; and he was glad to say both were doing good work. Hearty cheers were given for Mr. Mannering and Mr. Herring. The latter gentleman, in reply, requested all the staff to continue to assist him as they had hitherto done; and said if they did this, he would endeavour to make the Dover Gas Company as prosperous in the future as it had been in the past. The party left Hampton Court for Dover at 7.45, all heartily pleased with the excursion.

THE SHEFFIELD CORPORATION WATER-WORKS LOANS.—At the meeting of the Sheffield Corporation last Wednesday, the Town Clerk read a communication from the Local Government Board with reference to the application made by the Corporation to borrow certain sums of money for the completion of the water-works and for other purposes. Authority was given to borrow £87,844, instead of £127,641 applied for. In the first place the Local Government Board had not included £574 paid to some shareholders in the late Company who took capital instead of annuities, on the ground that the Corporation could borrow this without the sanction of the Board. With regard to the Damflask reservoir, the sum allowed was £13,882, instead of £16,440 asked for. With regard to the Oaken Clough extension, the Corporation not having yet arranged for the purchase of the land, the Board deferred their sanction to the loan for this purpose until such arrangements had been made. The loan of £11,550 asked for was accordingly not sanctioned. The Corporation applied for power to borrow £29,370 for the extension of water-mains, spread over three years; but the Board sanctioned the borrowing of £6000, with permission to apply again when this was expended.

THE MANAGEMENT OF THE WARRINGTON GAS-WORKS.—The *Warrington Guardian* says: "There is no doubt now about the determination of the Gas Committee to tender their resignation in a body (with one or, it may be, two exceptions) at the next meeting of the Town Council. The resignation does not necessarily imply that the services of all the members must be dispensed with. This would be a deplorable mistake. We hope to see not a few of them return to the Board, and give the ratepayers the benefit of their great experience and disinterested devotion to public duty. Their hands will be greatly strengthened by an infusion of fresh blood. We doubt not, at the same time, but that Mr. Haddock, the new Manager, will feel relieved from the incubus of a rather stereotyped system of managerial control. He should have a free hand; and if he is all that his best friends represent him, he will be able to make many alterations and improvements. That he has a large field to work on in this respect no one will deny. We understand," adds the *Guardian* (which has opposed the Committee's proposal to retain the late Manager's services), "that Mr. Paterson, with that high sense of honour for which we have always given him credit, has generally recognised the necessity for giving Mr. Haddock all credit for any improvements he should carry out, and has declined to accept the office of Consulting Engineer for one year. In acting as he has done, Mr. Paterson has, in a measure, given the severest blow possible to the Gas Committee. Further comment on this question in the meantime is unnecessary."

THE WOLVERHAMPTON CORPORATION AND THE BILSTON WATER SUPPLY.—At the last meeting of the Wolverhampton Town Council, Alderman Wright moved the adoption of the annual report of the Water Committee which showed that the profit on the last financial year amounted to £1776, and that the sales of water had been £523 in excess of those of the previous year. A new table was added to the report, from which it appeared that the quantity of water supplied to Bilston had risen from 80,769,375 gallons in 1886 to 119,573,228 gallons last year; and as a constant service was now being given to the people in the town, the supply would probably increase to 200 million gallons. Referring to the opposition by the Bilston Township Commissioners to the Wolverhampton Corporation Provisional Order, he said ostensibly it was against the application for power to increase the reserve fund from £5000 to £10,000 and to apply any surplus profits to the augmentation of the Improvement Fund. He could not understand why such objections should be raised, as if the powers were conceded they would not affect Bilston. It seemed, however, that the real objection to the Order was to be found in the fact that somebody had advised the Commissioners that they could secure a water supply at half the price they were paying to Wolverhampton; and they were therefore desirous of getting rid of their contract. An agreement, had, however, been entered into in perpetuity as to the water supply; and the payment could only be revised every 21 years. The Bilston opposition collapsed in the House of Commons; and whether they would go to the House of Lords remained to be seen. He thought it was scarcely likely that the Upper House would cancel an agreement so deliberately entered into, and confirmed only a few months ago.

COATBRIDGE GAS COMPANY.—The report of the Directors of this Company and the statement of accounts and balance-sheet for the half year ending June 30 last, prepared by the Manager and Secretary (Mr. T. Wilson), show that the affairs of the Company continue prosperous. The total income for the six months was £5489 12s. 9d.; and the profits were £2131 13s. 2d. This, with the balance of £247 17s. 5½d. brought from last half year, makes the sum of £2379 10s. 7½d. applicable to dividends. The unaccounted-for gas was at the rate of 16 per cent.; and the average illuminating power 26.4 standard candles. The half-yearly meeting of shareholders will be held next Tuesday, when the Directors will recommend the payment of maximum dividends at the rates of 10 and 7 per cent. per annum on the old and new stocks respectively, free of income-tax.

THE COST OF THE SOUTHAMPTON NEW WATER-WORKS.—At the last meeting of the Southampton Town Council, a return was presented from the Water Engineer (Mr. Matthews), showing the parliamentary estimate and the actual cost, including outstanding liabilities, on the Otterbourne works. The expenses strictly connected with the works were estimated at £55,690, and cost £50,090. The railway siding made by the South-Western Railway Company, the purchase of lands and easements, &c., were estimated at £4310, and their cost was £6471; bringing up the totals to £60,000 estimated, and £61,562 cost. Then the lining of the well, which was not contemplated in the estimates, came to £789; making the total cost of the works, £62,351. The net excess of the cost of works under the control of the Corporation, below the estimate, was £599 3s. 2d. The net excess of the cost of contemplated works, above the parliamentary estimate, was £1562 3s. 4d.

PROPOSED ADDITIONAL CAPITAL FOR THE FAVERSHAM GAS COMPANY.—An extraordinary general meeting of the Faversham Gas Company was held last Wednesday to consider a proposition submitted by the Directors to apply for a Provisional Order to authorize the increase of the Company's capital from £20,000 to £28,000. Mr. W. E. Rigden presided, and explained the reasons the Directors had for taking this step; one being that, on account of the new Local Government Bill, in view of which they, and every other gas company, felt it was incumbent upon them to place themselves in the strongest possible position. In the event of a District Council, or any other governing body, being placed in power, the Company would be in a much safer position with a Provisional Order, not only in regard to the right to lay down mains within and beyond the borough, but also if the local authority should open negotiations for the purchase of the undertaking. He moved a resolution embodying the Directors' proposition; and it was carried unanimously.

GWYNNE & BEALE'S PATENT GAS EXHAUSTERS AND ENGINES.

PLEASE ADDRESS IN FULL—

GWYNNE & CO.,ADDRESS FOR TELEGRAMS:
"GWYNNEGRAM LONDON."

HYDRAULIC AND GAS ENGINEERS, ESSEX STREET WORKS, VICTORIA EMBANKMENT, LONDON, W.C., ENGLAND.

TELEPHONE No. 2698.

Thirty-three Medals at all the Great International Exhibitions have been awarded to GWYNNE & Co. for Gas Exhausters, &c.

Only Medal at the Liverpool International Exhibition, 1886, for Centrifugal Pumping Engines.

They have never sought to make price the chief consideration, but to produce Machinery of the very highest quality.

The result is that in every instance their work is giving the fullest satisfaction.

They have completed Exhausters to the extent of 24,000,000 cubic feet passed per hour, which are giving unqualified satisfaction in work, and can be referred to.

ONLY 75 REVOLUTIONS PER MINUTE.

The above Engraving shows Two Engines driving Four GWYNNE & CO.'S PATENT NON-FLUCTUATING EXHAUSTERS, to pass 200,000 cubic feet per hour (without the slightest oscillation), at the EFFINGHAM STREET GAS-WORKS, SHEFFIELD.

Can be made, when desired, on their New Patent principle to pass Gas without the slightest oscillation or variation in pressure.

NO OTHER MAKER CAN DO THIS.

GAS VALVES, VACUUM GOVERNORS, REGULATORS, PUMPS, &c., &c.

Catalogues and Testimonials on application at the above address.

OXIDE OF IRON.

THE Gas Purification and Chemical Company, Limited, advise their friends that their only representatives for the Sale of Oxide are Mr. Andrew Stephenson and such Sub-Agents as may be accredited from the Head Office. They further state that the royalties possessed by them extend over an area of more than 850,000 acres, and are held for a long term of years. They employ their own overseers and labourers, and there are no intermediate profits between them and the consumer.

Address 161 to 163, Palmerston Buildings, Old Broad Street, LONDON, E.O.

JOHN WM. O'NEILL,
Managing Director.

ANDREW STEPHENSON, Agent for the Gas Purification and Chemical Company, Limited, 158, Palmerston Buildings, Old Broad Street, LONDON, E.C.

CANNEL COAL, &c.

JOHN ROMANS & SON, EDINBURGH. Gas Engineers, supply all the most approved SCOTTISH CANNELS; also FIRE-CLAY GOODS, CAST-IRON PIPES, and other APPARATUS for GAS AND WATER WORKS.

Prices, &c., will be forwarded on application to No. 80, St. ANDREW SQUARE, EDINBURGH, Scotland. No. 54, BERNARD STREET, LEITH.

CROWTHER BROTHERS solicit a trial of their IMPROVED SYSTEM OF RETORT SETTING. Can guarantee them to heat well, and the bottom Retorts to Carbonize as much Coal as those at the top. Constructed to burn Tar or Coke. Can be altered in a few minutes.

For particulars, write to 381, Mile End Road, LONDON, E.

GAS-WORKS of any magnitude leased, at premiums ranging from 5 to 10 per cent, according to the size of the Works. Gas-Works erected or re-modelled upon the most modern principles. Address GEORGE WELLER, Gas Engineer, St. Ives CORNWALL.

A YOUNG Man (aged 22), the Son of a Gas Manager, will be glad to meet with an appointment as CLERK, COLLECTOR, or MANAGER for Gas-Works at home or abroad. Good references; and security given. Address No. 1617, care of Mr. King, 11, Bolt Court, FLEET STREET, E.C.

GAS-FITTER.

WANTED, an active intelligent Fitter. Age not to exceed 30 years. Apply to the Gas Manager, Gas-Works, Malton, Yorks.

TO GAS ENGINEERING FIRMS AND COLLIERY PROPRIETORS.

WANTED, by a Consulting Gas Engineer, the LONDON AGENCY for any good Firm. The Advertiser has a good Gas Connection. Address, in first instance, No. 1024, care of Mr. King, 11, Bolt Court, FLEET STREET, E.C.

TO GAS MANAGERS.

THE Gas Committee of the Wantage Improvement Commissioners invite applications for the Office of GAS MANAGER and COLLECTOR to the Wantage Gas Works. The average product is about 7 million cubic feet; and the Gas Bills, amounting to about £110 per annum, are collected quarterly. Salary, £100 per annum, with House, Coal, and Gas. The person appointed will be required to keep the Gas Accounts, and to give a bond in the penalty of £200 for the due performance of his duties.

Applications, stating age, whether married, the situation lately held, to be sent on or before the 1st day of August to the GAS COMMITTEE, care of Mr. E. Ormond, Wantage, Berks.

TIMMIS & CO., of STOURBRIDGE

Make only the best quality of FIRE-CLAY RETORTS, BRICKS, TILES, & LUMPS. Also SPECIAL SILICA BRICKS, to stand great heats. All descriptions kept in Stock.

For Prices apply to JAMES LAWRIE and Co, 63, Old Broad Street, E.C., Sole Agents for London and District. Telegraphic Address: "EIRWAL, LONDON."

ALEX. WRIGHT & Co., 55, 55a, and 56,

MILLBANK STREET, LONDON, S.W. [Telegraphic Address: "PRECISION LONDON."] Makers of Wet and Dry Gas-Meters, Station Meters and Governors, Photometers, and Gas-Testing Apparatus, Test Gasholders and Meters, Registering and other Gauges, &c., &c.

* * See Advertisement on Page III. of the Wrapper of this week's issue.

W. C. HOLMES & Co., Huddersfield,

AND 80, CANNON STREET, LONDON, Contractors for Gas-Works complete, Makers of Gas-holders, Purifiers, Scrubbers, Condensers, Retort Fittings, &c., Improved Valves, Engines, and Exhausters. Also for Collingwood's Regenerative Retort-Settings.

* * See Advertisement p. 90 of last week's issue. Cablegrams: "Ignitor London." Telegrams: "Holmes Huddersfield."

"EXCELSIOR" TAR-BURNER.

TAR worth 30s. per ton for Burning.

Come and see and believe, or send for Burners complete, with Instructive and Descriptive Pamphlet, 16s. 6d.

Estimates given for Fixing and Starting, and satisfactory working guaranteed on application to THOS. BURTONSHAW, Gas-Works, CHIPPING NORTON.

BRISTOL UNITED GASLIGHT COMPANY.

THE Directors of the Bristol United Gas-

light Company are about to appoint a CHEMIST at each of their Avon Street, Canons' Marsh, and Stapleton Road Works, and invite applications for the appointments.

The candidates selected will be required to devote the whole of their time to the duties of their respective offices, and must be capable of making the usual tests and analyses required in Gas Manufacture.

The commencing salary in each case will be £80 per annum.

Personal canvassing will be a disqualification. Applications with copies of testimonials must be sent in, addressed to the Chairman of the Company, not later than Ten a.m. on Monday, the 30th of July prox.

JAS. V. GREEN, Secretary. Gaslight Offices, Canons' Marsh, Bristol, June 21, 1888.

BRISTOL UNITED GASLIGHT COMPANY.

THE Directors of the Bristol United

Gaslight Company are about to appoint two RESIDENT GAS ENGINEERS, to take charge of their Avon Street and Stapleton Road Works respectively, and invite applications for the appointments.

The candidates selected will be required to reside on the premises—where free House with Gas, Coal, and Water will be provided—and to devote the whole of their time to the duties of their respective offices. They must have had a thoroughly practical training, and be conversant with Gas Engineering in all its branches.

The salary in each case will be £300 per annum.

Personal canvassing will be a disqualification. Applications with copies of testimonials must be sent in, addressed to the Chairman of the Company, not later than Ten a.m. on Monday, the 30th of July prox.

JAS. V. GREEN, Secretary. Gaslight Offices, Canons' Marsh, Bristol, June 21, 1888.

IRISH BOG ORE OXIDE OF IRON.

GAS PURIFICATION.

BALE, BAKER, & CO., direct Importers from Ireland. Sample and Price on application. Spent Oxide and Sulphate of Ammonia purchased. 120 and 121, NEWGATE STREET, LONDON, E.C.

SULPHURIC ACID.

JOHN NICHOLSON & SONS, Chemical Works, LEEDS, specially produce this ACID for making SULPHATE OF AMMONIA of high quality and colour. Highest References and all particulars supplied on application.

ACETATE OF LEAD BOOKS.

TEST Papers and Solutions for Gas- Works prepared by R. D. Gibbs, Summerfield Crescent, Birmingham. Analysis of Coal, Oxide, and all Gas Materials.

HAVING been in the employment of the

Hastings and St. Leonards Gas Company for 27 years—21 of which I have made CHEMICAL OXIDE, FOR PURIFYING GAS (working at very low pressure), under A. H. Wood, Esq., late Engineer and General Manager—am prepared to attend at any works to show how it is made, or to send quantities already made.

Terms, samples, and conditions of JOSEPH RIDDLE, Chemical Oxide Maker, Clive Vale, Hastings, Sussex.

THE Directors of the Goole and District

Gas and Water Company have for Sale a set of four Cast-Iron PURIFIERS, each 13 ft. by 7 ft. 6 in. by 3 ft. deep, with 10-inch Connections, Centre-Valve, two Sets of Wood Grids, and Screw Lifting Gear.

For further particulars and to view, apply to JOHN WHITAKER, Manager.

Gas-Works, Goole.

FOR SALE, Four Purifiers 12 feet square

by 4 ft. 6 in. deep, with twelve 12-inch Valves Connections and Lifting Gear complete. Can be seen at work at the Stourbridge Gas-Works.

Also a double-action PUMP EXHAUSTER, for 10,000 feet per hour; made by Hanna, Donald, and Wilsou. Apply to W. NORTH, Gas-Works, STOURBRIDGE.

FOR SALE—A good Second-hand Gas-

HOLDER, 30 feet diameter by 12 feet deep; Five Columns, Trellis Girders, and Counterbalance Weights, in perfect condition. Also small CAST-IRON TANK and GASHOLDER, 20 feet diameter by 12 feet deep.

Apply to WILEY and Co., Gas Engineering Works, Commercial Road, EXETER.

TO TAR AND ROSIN DISTILLERS.

FOR SALE—Two Wrought-Iron Tar

STILLS, 1800 and 1600 gallons; three Cast-Iron ROSIN STILLs, with Covers and Condensers complete, and all in good condition; also several Wrought-Iron OIL-TANKS, from 300 to 7000 gallons. Must be immediately sold and cleared for alterations of Premises. No dealers.

Apply to F. MORRIS, Tar and Rosin Distiller, Plough Bridge, Rotherhithe, LONDON.

TAR AND LIQUOR.

THE Eccleshill and Bolton Gas Com-pany invite TENDERS for the surplus TAR and AMMONIACAL LIQUOR to be produced at their Works, together or separately, for One or more years, from the 1st of September next. Can be delivered in Contractor's tanks at the Station (G.N.R.) Coal carbonized per annum, about 1500 tons.

Tenders, sealed, and endorsed, must reach me not later than Saturday, the 28th inst.

J. MELLOR, Secretary. Eccleshill, near Bradford, July 14, 1888.

TUESDAY, JULY 24, 1888.

THE PRESENT CONDITION OF THE GAS INSTITUTE.

THE Gas Institute is at present in a state only to be properly described as critical; and some time—probably months—must necessarily elapse before all the steps required to terminate the crisis brought about by recent events can be taken. There is consequently ample opportunity for all necessary explanation and discussion of the position; and we therefore propose to devote this article, and one or two more if requisite, to an examination of the situation of the Institute as created by the proceedings of the Council and the legal effect of Mr. Bray's action, in order that the general body of members may realize how they are affected by these matters, and make up their minds as to their own conduct. Our motive

in undertaking this task is purely a desire to assist in composing differences, allaying irritations, and clearing up misunderstandings among the ordinary members of the Institute, which may have arisen out of the agitation so long kept alive by Mr. Bray for his own ends. We do not deceive ourselves for a moment into hoping that anything we can do will satisfy or soothe Mr. Bray; but we believe that the general body of members of the Institute must be heartily sick of the "Bray incident," and must desire nothing better than a return to the ways of peace and harmony in which they lived together before the Bray and Sugg feud disturbed the whole atmosphere breathed by gas engineers and managers.

Unfortunately, the *fiasco* terminating the lately attempted expulsion of Mr. Bray from membership of the Institute seems at a first glance to place yet a greater obstacle in the path leading to the resumption of fraternal relations among members. Whether this is really so, or whether the existent crisis can be taken advantage of for putting an end to all the cross-purposes that have troubled the peace of members and hindered the work of the Institute of late years, remains to be seen. The time for mutual reproaching between members holding opposite views is past, if it ever was present. We do not address these observations to those ill-conditioned persons, if such there be, who prefer strife to amity, envious disparagement of their fellows to mutual respect, and who rejoice like "ill birds" in "defiling their own nest." We address ourselves to the great bulk of gas engineers and managers of the United Kingdom, who, joining The Gas Institute for their own and the general good, have grieved to see it transformed into a bear-garden, and its meetings degraded into occasions for the venting of bitterness, hatred, and jealous passion directed to private ends. It must be admitted that peaceable men of this stamp have much to complain of. As at present appears, they have reason to accuse the Council of disastrously muddling the business which they were elected to manage in a proper manner. The Council must have been fully aware of the nature of the responsibility which they incurred when they proposed to the last general meeting to compulsorily remove Mr. Bray's name from the roll of membership. They knew that every loophole presented to the enemy in their procedure would be made the most of, to their own discredit and the plaguing of the Institute; and yet they made a miserable tactical blunder, which was exposed in all its naked hideousness on their first recourse to competent legal advice. Let us say this much, and then have done with it. If the Council had been properly advised in a legal sense, the present crisis would not have arisen. They made a shocking mistake, however, and they must bear the blame for it. The elaborate vote by which 126 members out of 188 recorded their agreement with the Council respecting the treatment to be accorded to Mr. Bray has been annulled by the effect of what is practically a slip in a matter of law; but it is impossible to overlook or minimize the consequence. Mr. Bray remains a member of the Institute, and for this reason the members of Council and others, to vilify whom he has abused the opportunity presented by his membership, must act up to their declarations, and retire.

It is a point of honour with those gentlemen whom Mr. Bray has attacked by name to withdraw from any society which contains him. Mr. George Livesey was the first to give expression to this resolve; and although the method and occasion chosen by him for making this declaration may not commend themselves to the individual judgments of all who have been associated with him in this matter, they agree with its spirit. The immediate effect of the legal proceedings of the 13th inst. will therefore be to diminish at a blow the Executive of the Institute to the President (Mr. Henry Woodall), and at most two or three members of Council—possibly not one. Certain of the more responsible office-holders—such as the Trustees, the members of the Finance Committee, and the Secretary—must remain at their posts to carry on the necessary routine business until they can be relieved; but henceforward not one of the members implicated in any way in the recent dealings of the Institute with Mr. Bray will take any part whatever in the society. We do not know how many will decide to resign, or how or when this decision will be carried into effect and made public. The fact, however, is certain; and we are able to say positively that some of the resignations are even now in the hands of the Secretary, and more will be ready for presentation at the next Council meeting, which is to be

held in a few days' time. No other course than severance from the Institute at the earliest moment is possible for any of these gentlemen possessing the most ordinary self-respect. How far the defection will spread, it is at present impossible to foresee. Members will, of course, exercise their right of private judgment upon this point, which is purely one of honour in which no man can desire to influence his fellow. Seeing, however, how widely Mr. Bray's allegations against gas officials identified with the Institute were cast in his latest pamphlet, it is very probable that a large number of engineers and managers of gas-works may decline to associate with him for the future. In any case, the withdrawals will be sufficiently numerous and important to create a crisis of the greatest gravity in the life of the Institute; and the emergency will be so pressing as to render it imperative for the President to call a special meeting in the autumn.

It is an extraordinary result of a blunder in law that the members who have received the support of large majorities of their colleagues in the Institute should be compelled to quit the organization, while the member of whom all but a small minority desire to be rid remains. So it is, however, and the situation must be faced. What may be the ultimate outcome of the present state of affairs is uncertain. The only positive fact to be dealt with now is that, as a consequence of Mr. Bray's legal victory, all the chief office-bearers and most of the leading men whose names have been identified for years with The Gas Institute, and before its day with the old British Association of Gas Managers, will throw up their connection with it. Is this a desirable result? It will be for the members who remain to answer this question by their conduct at the extraordinary general meeting to which they will be convoked by their President. Neither directly nor indirectly will the retiring members seek to control in the slightest degree the action of their former colleagues. If these should decide that they can carry on the work of the Institute better without their old leaders, the latter will not protest against such a decision. There will be no passion about it; but time, which tries all things, will show whether these men can better exist without the Institute, or the Institute without them. If they were superfluous, tyrants, a "clique," wire-pullers, self-seekers, and upholders of corrupt practices, as Mr. Bray and his followers have said of them many times, then the Institute is well rid of them and their works. If, on the other hand, they were the life and soul of the Institute—if they and their friends provided all the papers, contributed all the discussions, transacted all the tedious and formal business, and, by their character and willingness to impart their knowledge to the humblest inquirers, attracted to the annual meetings most of the hard-working members to whom these gatherings are something more than outings attended by unlimited free feasting and drinking—then with their retirement the organization must become moribund. Not one of them will move a hand to influence the verdict upon themselves which their whilom associates will return at the forthcoming special meeting. The votes to be cast then will not be their votes; the *agenda* will not be compiled by them. They have done with the Institute for good and all. Being fallible men, unused for the most part to the nice formalities of the conduct of a meeting under all the severities of the law, some of them have blundered. All that, however, is now beside the question. If they are no lawyers, they are at least competent guardians of their own honour; and in thus promptly renouncing fellowship in a society where their reputations have been attacked, they take the only course open to them without incurring the sacrifice of self-respect and public esteem. If it lasts, Mr. Bray may have The Gas Institute all to himself now, so far as they are concerned. He may bring forward in their absence yearly motions condemning them in all the relations of life, and may make speeches thereon likening them to every notorious criminal of the day. Nothing of this kind will affect them more, for they will have gone; and Mr. Bray will be at liberty to enjoy himself in his favourite pastime behind their backs.

MANCHESTER AND ITS NEIGHBOURS.

An attempt is being made by some of the customers of the Manchester Gas Committee to obtain a reduction in price. The dissatisfied are the Local Boards of the several townships beyond the city limits. They are of opinion that they and their constituents are unfairly taxed by the citizens, and have resolved to make a muted demand for more equitable treatment. The chief cause of complaint appears to be the differential rate; and the argument for its abolition is that

some neighbouring authorities—Salford and Stockport to wit—do not put such a tax upon the extra-municipal consumers in their supply districts. Whatever may be the result of the appeal, it is certain that the outside consumers are not too liberally dealt with by the Gas Committee. They take something like one-third of the gas produced at the various works belonging to the Corporation; and as, in addition to the differential price, they are, by the municipal system of financing, made contributors to the cost of lighting the city streets, besides bearing one-third of the charges annually reckoned for depreciation of works, the repayment of the mortgage debt, and the costly improvements paid for out of gas profits, they should be able to make out a very good case indeed for a substantial reduction. The question seems to be in some measure bound up with a much-discussed project for the extension of the city boundaries. From time to time, more or less fanciful schemes are put forth for the constitution of a "greater Manchester." Some of these actually contemplate a city whose borders shall be so extended as to include towns as far distant as Oldham and Rochdale; embracing an area of which the population would about equal that of the Metropolis itself. There is not the slightest prospect of any such proposal as this being carried into effect; but it is no secret that the City Fathers are anxious to bring the district more immediately surrounding the city into the very closest alliance with it. Places like Newton Heath, Gorton, and Moss Side, though not in the city, are really of it. Probably none but the rate collectors and the nuisance inspectors and their tribe know, to any degree of certainty, where the boundaries of the city end and those of its neighbours begin. Manchester is anxious to absorb these places; and is almost sure to do it some day; and the suspicion is entertained that, pending amalgamation, it does not disdain to make as much out of them as circumstances will allow. It is therefore not improbable that when the deputation go to the Gas Committee, they will receive a hint that relief from the burden they now have to bear may be obtained by joining hands with the city.

THE COUNTY GOVERNMENT BILL AND GAS AND WATER SUPPLY.

As will be seen from our "Parliamentary Intelligence" to-day, an attempt was made by Mr. Firth to add to the County Government Bill a clause empowering County Councils to promote and oppose Bills in Parliament without obtaining the consent of the ratepayers; and also to enable the prospective London County Council to promote Bills "for the purchase or regulation of the undertakings at present supplying water and gas to any part of London, or any of them, or for the provision of a new supply of water, gas, or light to London or any part thereof." This, as Mr. Ritchie pointed out, was tantamount to the repeal of the Borough Funds Act; and it was opposed by the Government upon this ground, and also for the reason that the whole question of Private Bill Legislation is unsettled. Mr. Firth's proposal was strongly supported in the House, especially with the modification of limiting the new public bodies to dealings with authorized undertakings, and restricting them from setting up competing works. Upon a division, the proposed clause was rejected by a majority of 8 only—a significant indication of the desire of Parliament to confer large powers upon the new County Councils. A second clause, casting upon the London County Council the duty of reforming the system of Local Government for the Metropolitan area, and including powers to regulate, acquire, or compete with existing Gas and Water Companies, was likewise rejected—the latter portion of it by a majority of 40. This is so far satisfactory. With regard to the general proposition that the provisions of the Borough Funds Act should not apply to the County Councils, we are disposed to agree to it, or the reason that the Act, as at present enforced, appears either farcical or unjust in the majority of cases. For once when it operates as a salutary check upon a rash Local Authority, there are ten instances of its appearing as a matter of form or as an obstacle to the carrying out of a sound piece of policy by such a body. And even when it comes into operation, it is more often as the tool of a noisy demagogue than as the weapon of a wise friend of the people. The more power there is entrusted to the new Local Authorities—within certain limits, of course—the more likely they will be to use this power with a due sense of responsibility. Provided that the County Councils are prevented from misusing public money to compete with private enterprise, we can see no good reason why the duty of promoting and opposing Bills in Parliament should not be confided to them; and thus the, in most cases, futile

restraints of the Borough Funds Act might be removed. This will certainly come in time; and it is as well to recognize the prospect at once.

THE REPORT OF THE JOINT COMMITTEE ON PRIVATE BILL LEGISLATION.

THE report of the Joint Select Committee of the House of Lords and the House of Commons appointed to inquire into the present system of Private Bill Legislation has been issued, and forms an interesting compendium of facts and opinions relating to this important subject. The Committee examined members of both Houses, as well as many official, professional, and other witnesses having experience of Private Bill business; several of them being representatives of associations or of local bodies interested in the subject. The report recites that the present system of Private Bill Legislation had its beginning in 1837, so far as the House of Lords was concerned; but the House of Commons did not fully apply it until 1855. It is admitted that the existing system is an improvement upon that which preceded it; but that improvement is still possible. It is a noteworthy fact (as remarked in the report) that every witness whose attention was directed to the point, whatever his view upon Private Bill Legislation in other respects, expressed or implied a preference for the Committees of the House of Lords, as composed of less fluctuating elements, and possessing a higher degree of *quasi*-judicial training and experience than the members of average Commons Committees. Other points in connection with Private Bill procedure—such as the argument for local inquiries, the expense of the present system, and its centralization—are brought out in the report, wherein also the alleged causes of expense are dissected and discussed. It appears that the Private Bill business is a paying one for the nation, seeing that the fees paid by suitors have amounted, on an average of the past ten or twelve years, to £58,000 per annum for both Houses, while the expenses have not exceeded £20,000 a year according to the highest estimate. After going into all these matters, the Committee observe that it remains for consideration whether the time has not come for a more comprehensive reform of Private Bill business than any that has been adopted since 1837. Broadly, three proposals were put before the Committee. The first was for the establishment of Commissions entrusted with the powers and functions of Private Bill Committees; the second, for Joint Committees of both Houses; the third, for an extension of the system of Provisional Orders. It is remarked that the demand for a Commission, with the possibility of local inquiry, was preferred by a majority of witnesses from Scotland and Ireland, but condemned by a powerful group of witnesses representing the most experienced authorities. As against the proposal for Joint Committees, it is remarked that while they would probably save the expense of a second contest in the case of one-fifth of the total number of opposed Bills in the year, they would fail to satisfy the demand for local inquiry, and would afford a less measure of relief to members of the House of Commons than is commonly supposed. On the whole, the Committee are brought to the conclusion that, although a Commission must necessarily be an experiment, it presents the best hope of an adequate solution of the difficulties of the situation. The cost of a competent tribunal would probably be considerable; but it might be provided out of the £40,000 annual surplus of suitors' fees. Here the recommendation of the Committee ends. They leave to the Government the duty of carrying it out; and, under these circumstances, it will be some time before anything further is done.

LORD R. CHURCHILL'S BILL AGAINST "COMMISSIONS."

THE Bill of Lord Randolph Churchill, for rendering the acceptance of "commissions" by officers of corporate bodies a penal offence, has been withdrawn in consequence of the somewhat unintelligible opposition of the member for the Camborne Division of Cornwall, who was understood to hold views of his own respecting the manner in which this matter should be dealt with. As, however, since this triumph of obstructiveness, the honourable member has been suspended for a month for misconduct towards the Speaker, there is no prospect of his doing anything in this line during the short remainder of the present session. What will be the upshot of the business remains for the time uncertain. Lord Randolph's proposals did not err on the side of mildness; and were perhaps open to the reproach of an attempt to make political capital out of the existing condition of public feeling aroused by the disclosures in the course of the inquiry of the Royal Commission upon the proceedings of the Metropolitan Board of Works. If one were to inquire too

closely into this aspect of Lord Randolph's action, however, the result would not be of much practical value. At a time when the manufacture of political capital is the main occupation of statesmen of all parties, it would be sheer pedantry to disparage the merits of any proposed piece of legislation on the ground of its presumptive bearings upon party politics. It is sufficient for the occasion to note that Lord Randolph's reforming zeal has suffered a check; but we do not suppose that the present irritation of the public mind on the subject of official peculations will be allayed until some legislative measure has been passed to remove the existing uncertainty respecting the application of the forms of law to those offences against the moral code which have of late shocked the public conscience. In the eyes of many people, the pending proceedings with reference to the Metropolitan Board of Works, marked as they are from week to week by summary dismissals of the incriminated officials of that remarkable body, will be deprived of their point if they do not result in the placing of some legal obstacle in the way of the occurrence of a similar scandal in other quarters.

END OF THE WARNER LIBEL CASE.

THE unpleasant case of libel upon Mr. W. J. Warner, of South Shields, has been satisfactorily terminated by the unqualified withdrawal of all imputations, as will be seen from the report of the proceedings at the Durham Assizes appearing in another column. The facts are few and simple. Richard Cunliffe, at one time employed under Mr. Warner as inspector of a gasholder tank in course of construction, was discharged from the Company's service some time after the termination of the work in question, and a claim for overtime preferred by him was disallowed. For this and for failure to obtain further employment under the Company, Cunliffe bore a grievance against Mr. Warner, whom he accused, in a letter to one of the Directors, of managing the business confided to him in a "deceitful and unscrupulous way," and of "blundering" in such a manner that the tank cost £2000 more than it should have done. In the usual fashion of libellers, Cunliffe protested that he was in possession of proofs of his allegations; and the result of his accusations was an action by Mr. Warner to clear his character. Cunliffe was committed for trial by the South Shields Magistrates, as reported in the JOURNAL for May 1 last; and when the case came before Mr. Justice Cave, yesterday week, the prisoner found he had no option but to throw himself upon the prosecutor's mercy. It was made abundantly clear that Mr. Warner entertained no vindictive feeling against Cunliffe, whose aspersions, as was confessed, were exaggerated under the effect of a partial view of the facts, and were published under a sense of personal grievance. The case having terminated in this way, the only thing to regret about it is that it was ever necessitated by Cunliffe's ill-considered attack upon his former chief. Mr. Warner deserves the sympathy of his friends and professional colleagues in the position in which he was placed by the rancour of a discharged subordinate; but it must be admitted that the incident has ended in the best possible way. It would not have been any gratification to Mr. Warner, if the case had gone to its end, to reflect that the vindication of his own character had entailed the imprisonment, and perhaps the ruin, of a foolish clerk of works; and Cunliffe has had to pay smartly enough for learning that it is not always safe to asperse the reputation of others upon partial "evidence," which, when tested, amounts to nothing more than an uncharitable opinion.

THE balance to the credit of the net revenue account of The Gas-light and Coke Company will (subject to audit) enable the Directors to recommend the payment of a dividend for the past half year at the rate of 13 per cent. per annum; carrying forward to the next account a balance of £277,563.

WE are pleased to announce that M. Albert Ellissen, the immediate Past-President of the Société Technique du Gaz en France, has been nominated an officer of the Legion of Honour—a promotion from the rank of chevalier, which was conferred upon him in 1871. During the recent visit of the members of the Society to England, many of our readers had an opportunity of becoming personally acquainted with M. Ellissen, who, from the position formerly held by him as Engineer of the Paris Gas Company, and his connection with various Continental gas undertakings, has for some years taken a leading place in our industry. Apart from this, M. Ellissen is a member of the Council and Secretary of the Society for the Relief of Wounded Soldiers, and Vice-President of the Board of Directors of the *Petit Journal*. This is an instance in which English and French gas engineers will cordially unite in offering congratulations to a professional colleague on the distinction conferred upon him.

Water and Sanitary Affairs.

THE prosecution by the Southwark and Vauxhall Water-Works Company of a person named Linsey, reported in the last issue of the JOURNAL, raises some curious and very interesting considerations. The accused was charged with stealing a quantity of the Company's water; and his Counsel boldly contended that this act, even if proved, did not constitute a criminal offence. According to the learned gentleman's argument, a man can no more steal water than he can steal air. Each of these elements, he urged, is free to everybody. Assuredly this is a startling proposition in regard to water. We are not surprised that the Chairman of the Surrey Sessions (Mr. H. Yool) should have been sceptical as to its soundness; for, apart from the decision which was cited in support of the prosecution, common sense and common law should be strong enough to govern the case which was disclosed by the evidence. It may be conceded that, in some circumstances, water would not be the subject of larceny; but, under altered conditions, we cannot doubt that to steal, take, and carry away any quantity, small or great, will bring a man within the purview of the criminal law, in the same way as if he had wrongly appropriated any other description of property. An analogous case is not by any means difficult to find. Larceny cannot be committed of wild animals—in which there is no property—as hares in a forest, rooks in a rookery, or fish in an open pond or river. But where animals *feræ naturæ* have once been reclaimed, tamed, and confined, to take them from their lawful owner is to be guilty of larceny at common law. Thus, deer enclosed in a park, or fish in a trench or ornamental pond, cannot be taken with impunity; and, in like manner, water (which probably anyone might use or remove when found in an open river or lake) acquires the character of private property when reduced into possession by a company or an individual. It may then, as we submit, become the subject of larceny. It is beside the point to say that there are various statutory penalties to which a water company can have resort. Why should they be restricted to these remedies, which in some instances might be wholly inadequate? In other words, why should not water-works proprietors, in regard to their common property, possess the same rights, and enjoy the same protection, which the law affords to other companies and to individuals in every rank of life?

In connection with the case tried at the Surrey Sessions we do not desire to offer any opinion, although it would seem that the Chairman was not a little surprised at the verdict of "Not guilty" which the jury, in their wisdom, thought fit to return. It is with the general aspect of the question that we concern ourselves, in the belief that when water is stored by a water company, or pumped into their mains or pipes, it must be acknowledged to be the property of that company; so that a man can have no greater right to take the water without paying for it than he would have to appropriate the main or pipe itself. In the case which was cited during the recent prosecution, two of Her Majesty's Judges ruled that to obtain a supply of water surreptitiously constituted a misdemeanour. Notwithstanding this decision, Counsel for the defence at the Surrey Sessions argued that the offence alleged against his client was not indictable. It is true that in the prosecution in which the Judges considered the point, the prosecutors did not possess any statutory powers; whereas a company such as the Southwark and Vauxhall Company, incorporated by Act of Parliament, may recover specified penalties in a summary manner. But this, we conceive, can make no possible difference. Neither the Water-Works Clauses' Act, 1847, nor any other statute, professes to limit the general rights of property-owners or to exclude those common remedies which are prescribed by the general law of the land. As regards the technical proof of the taking and "carrying away" of water, we apprehend that very slight evidence should be sufficient. This, at any rate, is the case with regard to a theft of gas. In a reported case of a gas consumer charged with fraudulently obtaining a supply by fixing a communication pipe from the inlet to the outlet of the meter, so that a portion of the gas passed to the burners unregistered, it was held that the opening of the stop-cock thus letting gas pass into the communication pipe, was sufficient to constitute a legal *asportavit*, and that an act of larceny had been committed. A similar mode of reasoning would, it seems natural to suppose, be equally applicable where a man is charged with stealing a supply of water by means of a like device.

Essays, Commentaries, and Reviews.

GAS AND WATER COMPANIES IN THE STOCK MARKET.

(FOR STOCK AND SHARE LIST, see p. 177.)

DURING the past week there has been a slight reaction from the improving tendency which characterized the preceding week. Some of the chief markets have fluctuated from day to day, and close fractionally lower; foreigners being affected by a less easy feeling as to the meeting of the two Emperors. Business generally has been restricted; and some departments were very quiet. Money is harder, owing to the demand for gold. In the Gas Market there has been more activity than in any week for some time past. Gaslight "A" has naturally been well to the front. The announcement on Tuesday of a 13 per cent. dividend had been generally anticipated, and discounted in advance; but the stock rose a little more upon the actual certainty. The reduction of 3d. per 1000 cubic feet represents a loss of rental equal to about £100,000. The increase of the dividend absorbs about £20,000; and, in addition to this, the profit and loss balance is augmented by £47,000. The aggregate, £67,000, thus shows a recouping of at least 2d. per 1000 feet. The accounts will probably indicate that the bulk of the profit proceeds from improved residuals and economic expenditure, rather than from a largely increased sale of gas. All the preferred and maximum stocks, and some of the debentures of the same Company, have also advanced. South Metropolitan have all been dealt in at well-advanced prices. Commercial old has recovered 2 more. Brentfords are up, in view of the approaching payment of the dividend. Some of the foreign undertakings have been active—especially Imperial Continental and Continental Union. The former is in better demand, and closed firm at a rise of 3. European has declared a 13 per cent. dividend. This is 1 per cent. higher than it divided a year ago; and that was itself 1 higher than the previous rate. The Company have thus made a rapid advance. Business in the Water Department has been above the average, and prices continue to creep up by small degrees. The daily operations were: Monday's Gas transactions were moderate. Gaslight "A" was firm, without advancing. The 6 per cent. debentures and Imperial Continental improved 1 each. Water was quiet and unchanged. On Tuesday nothing was much dealt in but Gaslight "A," which was very brisk, and touched 262—a rise of 2. All the 10 per cents. rose 2; and the "H" and the 6 per cent. debentures, 1 each. South Metropolitan "A," Commercial ordinary, and both Brentfords also advanced 2. South Metropolitan "C" improved 5. European new gained $\frac{1}{2}$. Water was as before. Gas was very busy again on Wednesday. Gaslight "A" was done once at 263—the highest point reached; and buyers were 1 better. Bahia rose 1. In Water, Chelsea and Lambeth were frequently dealt in at good prices. On Thursday, Gaslight "A" was quieter and steady. Imperial Continental rose 1. Water was also quieter at a rise of 1 in Chelsea and Lambeth 10 per cents. Business in Gas was further restricted on Friday; but prices continued to rise. All Gaslight preferences and maximums gained from 1 to 2 each; and South Metropolitan "A" and "B," 1 each. Water was stronger; Grand Junction improving $1\frac{1}{2}$, and East London and Southwark ordinary, 1 each. Gas was very quiet on Saturday, except South Metropolitan. The "A" rose 1; and "B," $1\frac{1}{2}$. Imperial Continental were 1 higher. Water was quiet and unchanged.

ELECTRIC LIGHTING MEMORANDA.

THE JUDGMENT IN THE EDISON AND BRUSH LAWSUIT—THE AFFAIRS OF THE MAXIM-WESTON COMPANY—THE ELECTRIC LIGHT AT LEAMINGTON—RUMOURS OF FRESH ELECTRIC LIGHTING SPECULATIONS.

ON Monday last week a most important decision was delivered by Mr. Justice Kay upon the Edison incandescent lamp patents, the effect of which is apparently to destroy the Edison monopoly. It was a tremendous action—the Edison and Swan Company being plaintiffs, and the Brush Company the real defendants—and it occupied the attention of the Court for 21 days; every available professor of physical science and electrical expert being called on one side or the other. The costs must have been enormous; and the issue was of the gravest moment. The two patents upon which the action was fought are those of Edison of 1879, for an incandescent lamp, and Chesebrough of 1878, for "flashing" the carbon filaments of such lamps. They were the same patents that were maintained in the prior action of the plaintiffs against the firm of Messrs. Woodhouse and Rawson; and consequently the owners may have been pardoned for feeling some confidence in the result. The case was gone into very much more fully, however, on the last occasion; with the result that the judge pronounced against the Edison patent, with costs, and for the Chesebrough patent, also with costs. There was a good deal that was very remarkable about the trial, apart from the amplitude and cost of the hearing. The Judge had occasion to complain very strongly of the manner in which some of the highly-paid experts gave their testimony; the proverbial tendency of these gentry to swear according to their instructions being unusually conspicuous. It is not without a gleam of inward satisfaction that hard-working and practical men, who do not happen to have any practice in the Courts, can observe such an instance as this, when reproof and discomfiture were the portion of several most portentous personages—Fellows of the Royal Society, professors, and other great men of modern science. Mr. Justice Kay accused some of these luminaries of deliberately attempting to mislead the Court; and he had so little confidence in them that he directed several crucial experi-

ments to be made under independent supervision during the progress of the hearing, with a view to settling points upon which the expert evidence was contradictory. The judgment against Edison's patent went on the usual ground, that the process described in the specification had not been actually carried out, but that the lamp as made and sought to be protected under the patent was, in reality, something quite different. As for the Chesebrough patent, this now appears to be as strong as Edison's patent is weak; so that the "flashing" of incandescent lamp carbons in an atmosphere of hydrocarbon vapour, to equalize their thickness, remains a monopoly of the Edison and Swan Company. Of course, it is possible to make incandescent lamps without flashing; and thus the manufacture of these articles will be in a great measure free from the obligation to pay royalty to the Edison people, unless the judgment now in question is reversed on appeal.

The Maxim-Weston Company continue to hold extraordinary general meetings every few days, with a view to the settlement of the difficulties into which the concern has been plunged by the disputes between the Chairman, Mr. Hugh Watt, M.P., and the shareholders. The most recent of these took place on Thursday last, for the purpose of appointing additional Directors; and although the proceedings were not quite so riotous as on previous occasions of the same kind, they were anything but tame, as the business to be done was distinctly antagonistic to the Chairman. Five new Directors were added to the Board; and the Chairman accepted the situation with a tolerably good grace, considering all things. He amused the meeting with an oration upon the past, present, and future of electric lighting, according to which the prospects of the industry were never so bright as they are to-day. He declared that the Company are in negotiation with innumerable railway companies, steamship-owners, and shippers for installations on the Maxim-Weston system—all of which must, of course, be taken for what it is worth. It is usually a bad sign when the Chairman of an Electric Lighting Company tells the shareholders that inquiries are coming in from all quarters, and that the Company's works are in a position to meet all requirements.

There is a tremendous amount of assertion and contradiction in Leamington on the not very abstruse point as to whether the street lighting by the local Electric Lighting Company is a success or a failure. The Company, of course, contend that the service is very good; but some of the members of the Town Council entertain a contrary opinion. The real problem is of more than local interest, since it is nothing less than the question of the efficiency of incandescent electric lamps for the lighting of open spaces. These lamps have been tried on the Holborn Viaduct, and are at the present moment used at the Victoria and Waterloo Stations, and one or two other similar places in London. Experience shows that somehow these lamps do not give as much serviceable light under such conditions as gas; and accordingly, where anything like good lighting is required, two of them are used in place of one gas-lantern. In small interiors, even in Leamington, the incandescent lamps do very well; and as long as they are kept up with reasonable regularity of illuminating effect, people like them. They are comparatively inefficient out of doors, however, and for lighting large areas, not merely in Leamington but everywhere else. It may be unscientific to say so, but the fact remains that the lamps lack diffusive power, and their light seems to be smothered in a large dark space.

Rumours continue to spread of a considerable expansion of electric lighting speculation, following upon the recent alteration of the law governing the duration of Provisional Orders. It is stated in one quarter that a scheme is afoot for the extensive introduction of Westinghouse and other new American systems of electrical supply into this country; it being felt that something altogether fresh is desirable to arouse interest in the electric light business. The public mind has been clogged with Brush, Edison, and other promises, that have never been fulfilled in actual working; and it is imagined that greater credence may be extended to an altogether new comer. The idea is not a bad one; but it remains to be seen whether there is really anything in it.

TITLE AND INDEX TO VOL. LI.—Owing to the length to which it has of late been found necessary to extend our half-yearly index, it will not, for the future, be issued as part of the JOURNAL, as hitherto. A Title-page and Index to Vol. LI. (January to June, 1888), have been prepared, and will be ready next Thursday; and a copy will be forwarded post free by the Publisher on receipt of a post card.

AN ATTEMPT AT ELECTRIC LIGHTING AT MATLOCK.—The Directors of the Smedley Hydropathic Company, at Matlock, are introducing the electric light into the public rooms of their establishment. On the 28th ult. (but some considerable time after it was originally expected the installation would have been completed) the light was turned on for the first time. By way of giving suitable *éclat* to the event, a band of music was engaged for the occasion, and a number of persons were invited to be present. The engine was started in the afternoon, and was worked at a low pressure until about eight o'clock in the evening, when an order was sent to the driver to do his best. He obeyed; and in a few minutes afterwards there was a great smash. The two wheels of the countershaft broke—various fragments flying through the windows into the street, to the alarm of the passers by. The dynamo also broke; and, of course, the light suddenly went out. The despised gas had to be lighted, and is now in use again; and we understand is likely to be for some weeks to come.

THE QUESTION OF COKE.

THE recent inquiry of the JOURNAL respecting the cause or causes of the increased demand for coke that has marked the past year, has so far only elicited one response, which will be found in our "Correspondence" columns to-day. This letter is interesting as a reminder of the difference between the markets for coke in England and on the Continent; and it is possible also that it contains a partial solution of the mystery of improved coke sales in the United Kingdom, in the suggestion that consumers of fuel are at last beginning to appreciate the value of coke for general manufacturing purposes, and especially in connection with the production of fuel gas. It is impossible to say how much reason there may be in this observation; but it is at least possible to state that it is very apposite. It is a fact that fuel users in Great Britain have never yet given the full money value for coke; and it would be a very good thing if the complaint could be regarded as no longer called for. Unfortunately, we cannot flatter ourselves that such a sweeping change in the views and habits of English fuel consumers can have taken place within so brief a time as a single year. Movements of this kind are generally slower in their rate of progress through a whole nation; but, of course, we cannot say that nothing of the kind is in operation. That there is plenty of room for it is easily shown. In the number of the JOURNAL for December 18th last (p. 1058), there is a report of a trial of breeze and coke for steam raising at the Shoreditch station of The Gaslight and Coke Company, conducted under the auspices of Messrs. Bryan Donkin and Co., where it is recorded that 1 lb. of coke evaporated 11.03 lbs. of water from the temperature of the feed, which was 202° Fahr. The cost of the fuel was taken at 14s. 2d. per ton; and at this price the cost of evaporating 1000 gallons of water, for fuel only, was 5s. 8½d. A less favourable experiment at another station of the same Company gave an evaporative duty for coke of 9.5 lbs. per ton, and the cost of evaporating 1000 gallons of water then worked out to 7s. 0½d., with coke at 15s. per ton. This standard of comparison—the cost of evaporating 1000 gallons of water—is recommended by Messrs. Donkin as convenient for comparison; and it would be beneficial if fuel users would pay more attention to this point than they do. Without going any further, we may claim from these tests a very respectable evaporative duty for coke burnt under ordinary conditions, and do not hesitate to declare that it shows an economy of from 15 to 20 per cent. as compared with the steam coal ordinarily used in London.

It must be conceded that the more coke is sold out of the yard in the ordinary way, the dimmer becomes the prospect of gas companies taking to gasifying it and distributing the product. At one time, when the future of the coke market looked very black, and there did not appear to be any hope of the demand rising to the absorption of the increased supply resulting from the extended consumption of gas, we seriously discussed the question whether it would prove desirable for gas makers to convert their surplus coke into fuel gas. Circumstances have changed since that time; and the question of fuel gas from coke, to be made on the gas-works, has receded into the background. We do not think, moreover, that the increased demand for coke is due to any remarkable development of the use of fuel gas by manufacturers. Indeed, it would not be surprising if one should hear that the people interested in fuel gas processes and apparatus have reason to complain of poor business. It seems tolerably clear that the extension of the use of the weaker kind of fuel gas—generator gas—for manufacturing purposes is not very rapid just at present; and the drawback of the more powerful varieties of fuel gas is that the difference of cost between them and coal gas in most manufacturing centres of the United Kingdom is not so great as to render them very preferable to the latter as fuel. Cheap coal gas is undoubtedly forcing fuel gas into the background; and the retirement of fuel gas leaves the disappearance of coke heaps to be accounted for in other ways.

We fear there is nothing else for it but to fall back upon the old generality of improvement of trade. There has been more work done in the country of late; the coal market has been "hardening," and coke has been purchased largely. After all has been said, however, one feels that such commonplaces are unsatisfying, and that much would be given by any man of business for the key to the industrial movement of which the demand for coke has been only a symptom. The immediate question for coke producers to consider, however, is whether they are in a position to "rest and be thankful," in the knowledge that the true value of coke is at last appreciated by consumers, and that they will never have a glut of the product any more. The reply to this inquiry from a disinterested observer of the facts, notwithstanding the optimism of our Spanish correspondent, must be in the negative. These casual clearances of coke heaps must not cause any relaxation of the efforts that were undertaken some years ago to improve the demand for coke by breaking it for domestic and manufacturing purposes, and to bring its capabilities under the notice of steam users. Especially there is one point in connection with the burning of coke in steam-boilers that may profitably receive more attention than has hitherto been given to it. We allude to the application of forced draught to coke-burning furnaces. This is rather an important question, since the advantages of forced draught for marine and mill engine boilers has been recognized in so many instances. It is quite possible that the use of a blast, if only under a pressure of about ½ inch of water, may render coke a successful and economical fuel, where it has been tried and found wanting without such an aid to combustion. The precise conditions under which coke is capable of supplanting bituminous coal for steam raising require to be understood

before success can be depended upon. The importance of a good draught for burning coke economically is universally granted; but what we should like to be sure of is the extent to which artificial draught can be made to modify the steaming capacity of a boiler burning coke. Of all the experiments that have been made with forced-draught furnaces, not a single one, so far as we are aware, has been with coke, which is the fuel of all others that seems best qualified for such treatment. This is not the first time that the suggestion has been offered in these columns, of the desirability of experiments being instituted to establish the influence of forced draught upon coke furnaces; and we shall not lose sight of this matter.

The greater popularity of coke as fuel for household use on the Continent, at least in certain places, as compared with England, is easily accounted for. People who are accustomed to burn wood-charcoal for cooking purposes can be persuaded to consider the merits of mineral charcoal—that is to say, coke—when it is offered to them in a suitable condition for use. The general dearthness of fuel, especially coal, in most Continental countries is also a powerful inducement to the people to make the best of anything that will burn. These and other considerations, however, must not conceal from one the fact that those Continental gas companies which make most out of their coke are, as a rule, those who deserve it best by their efforts to create a market for this residual. It is true that they found a public accustomed to close charcoal stoves, who could consequently be more easily persuaded of the advantages of coke than the people of England, who are in the habit of cooking their food, and warming themselves, by the aid of ample, roaring, open coal fires. It is also true, however, that many of them studied the question thoroughly, and offered their customers not merely the fuel, but also the best stoves and grates in which to burn it, that had ever been seen. What English gas companies have done for gas-cooking stoves, foreign gas companies have done for coke. Debarred from much hope of selling gas for cooking and heating purposes, on account of the prices entailed by the concession system under which they exist, these gas companies have taken delight (as well as profit) in showing what they could do to create a demand for, and push the sale of coke. The Paris Gas Company are honourably distinguished in this respect; but there are others not far behind them. It may be too much to expect English gas companies to adopt a similar course; but at least let us not overlook the benefit that it has conferred upon both the producers and consumers of coke when it has been tried.

THE MANAGEMENT OF THE WARRINGTON GAS-WORKS.

As the result of the recent agitation in reference to the management of the gas-works and of the decision of the Town Council at its last meeting (see *ante*, p. 81), the Warrington Gas Committee will, it is stated, resign in a body. The Council did not, it will be remembered, boldly reject the Committee's proposals; but it so minimized and restricted them that the Committee are understood to consider the resolution as equivalent to a vote of censure. With one or two exceptions—who represent, it may be presumed, the dissentient minority—they are therefore determined to seek a position of greater freedom and less responsibility. Another rumour (given with an air of authority) is that Mr. James Paterson will also decline the somewhat doubtful honour which the Council sought to confer upon him by appointing him Consulting Engineer of the gas-works for one year only. If these statements are well founded, it is obvious that an important crisis, involving probably great changes of policy, is about to occur in the history of the Warrington Gas-Works. As to what will be its result, it would be idle to speculate. Those who have been chiefly instrumental in defeating the policy of the present Committee are as jubilant as if the millennium were at hand. It seems to be imagined that it is all the fault of what is called "a rather stereotyped system of managerial control" that the price of gas is not so low as in some other towns, and that the works do not yield immense profits. All this is now to be changed; and Warrington will have cause to rejoice that it has got rid of its old servants and their antiquated ways. Those who write and speak in this style never imagine that they are scarcely just, to say nothing of being generous, to the men who have served them faithfully and well in the past. Like many other works, those at Warrington are burdened with a heavy capital; and however capable the management may be, there will still be this incubus to be borne. The now Committee and the new Manager will be no better off than their predecessors in this respect, unless there should be an extraordinary increase in the consumption, such as would employ the works to their fullest capacity, and bring the capital charges to something like an average percentage on the quantity of gas made. A development of this kind, is of course, to be looked for; but it is much more likely to be of slow and steady growth than to come by leaps and bounds. There is, however, something particularly ungracious in these attempts to pit the old against the new Manager. Mr. Haddock, who is now in charge of the undertaking, has been a pupil of Mr. Paterson's, and has been for some years associated with him in the management of the works, and he will, no doubt, be amongst the first to acknowledge the very great ability of one whom all gas engineers are proud to look up to as one of the fathers of the profession.

The proposal of the Gas Committee which has excited so much feeling, and is to lead to those great changes, was, after all, a very modest affair. It certainly did not err on the side of extravagance. Mr. Paterson was desirous of retiring from the active management of the works—a position which his enfeebled health rendered some-

what irksome; and his resignation necessitating certain changes, the suggestion was made that the duties of Manager and Secretary should be divided, and the whole of the appointments rearranged. Direct oversight of the works was to be vested in Mr. Haddock; and the Committee wished to give him the assistance of the late Manager as Consulting Engineer. This office Mr. Paterson was willing to accept at the very modest remuneration of £100 per annum; and as, apart from this, the changes contemplated meant a saving of £200 a year, the Committee doubtless congratulated themselves on having done very well indeed. Somebody seems, however, to have seen in the scheme a means of raising a clamour; and the result was one of those tremendous "storms in a teacup" such as are wont to disturb the calm of provincial life. It is not the first time that an agitation of this kind has transcended in its effects the very small issue involved; for, indeed, it frequently happens that the noise made is in inverse ratio to the importance of the question to be decided. Gas became all at once a subject of absorbing interest to a large number of the inhabitants of Warrington; and the local papers are given up for the time to the discussion of the one topic. The Committee were suspected of harbouring a desire to pension off an old servant by finding him a sinecure post; and great numbers of people suddenly displayed immense anxiety to denounce the wickedness of this proceeding, and show how the gas-works should be managed. It was in vain that the Committee pointed out that they are to have from Mr. Paterson valuable services in return for their money, and that the outcome of their proposals would be a real saving. The commotion had its effect on the Council, and though the attempt to carry a resolution against the appointment of Mr. Paterson failed, the opponents of the change succeeded in binding the Committee to the necessity of reopening the whole question at the end of twelve months. Rather than do this, the Committee are to go out of office, and Mr. Paterson declines the offer so grudgingly made, and both, we quite think, do well. Their decision will, at all events, give the Corporation an opportunity of rescinding the resolution already passed, if on second thoughts it should discover that it has acted ungraciously and without consideration of the consequences of adopting a merely "penny wise" economy. Since the above was in type, we learn that it is the intention of the Committee to ask at the next Council meeting for a vote of confidence; and that, failing this, they will adhere to their resolve to resign.

DEATH OF MR. J. MATTHEW, OF DUNDEE.—We regret to record the death last Tuesday, in his 76th year, of Mr. James Matthew, the Treasurer of the Dundee Gas Commissioners. Mr. Matthew had been in failing health for about two years before his death, which appears to have been accelerated by the loss of his wife. The deceased gentleman was originally in business in Dundee as a spinner; but he left this to take the appointment of Accountant in the office of the Dundee and Perth Railway Company. This he relinquished in 1860 to enter the service, as Cashier, of the Dundee Gaslight Company; and when, in 1868, the gas-works were transferred to the Gas Commissioners, he was appointed Treasurer—a position which he held till the time of his death. He was a man of marked integrity; discharged his onerous and responsible duties with care, punctuality, and precision; and enjoyed the fullest confidence and respect of the Commissioners and the general public. At a special meeting of the Commissioners held on Wednesday, general regret was expressed at the loss they had sustained; ample testimony being at the same time paid to Mr. Matthew's excellent qualities. The meeting was called to appoint an interim Treasurer; and Mr. Strachan, who was for many years in the service of the Gas Company, and has long been the principal clerk in the office of the Commissioners, was selected.

THE HALIFAX GAS COAL CONTRACTS.—The Halifax Town Council were engaged *in camera*, on Monday evening last week, in dealing with the serious allegations which have lately been made in connection with the coal contracts of the Corporation. It will be remembered that when these charges were brought before the Council at their meeting on the 4th inst. (see *ante*, p. 79), it was decided that the whole of the correspondence, which was given in the issue of the *JOURNAL* for the 3rd inst., should be referred to a Sub-Committee, consisting of the Mayor, Alderman Ramsden, and the Town Clerk, with instructions to take Counsel's opinion thereon, and report. A case was accordingly drawn up, and submitted to Mr. R. S. Wright; and his opinion was read to the meeting. We learn from a local paper that, in substance, it was as follows:—(1) The letter of Mr. Ellis Lever was not considered to be libellous. (2) The letter of Mr. Fox was distinctly libellous, although it was doubtful whether any action could be founded upon it, as no persons were named. (3) The paragraph in the *Pall Mall Gazette* was also libellous; but, in this as in the previous case, there was the difficulty of fixing the libel, as no persons were mentioned by name. After some discussion, it was resolved to leave the matter in the hands of the Sub-Committee, with power to take such steps as they might consider expedient with the object of bringing about a satisfactory investigation of the charges. In the course of the discussion, it was stated that the person referred to in Mr. Fox's letter as receiving commission on the coal purchased for the gas-works was Mr. Emor G. Wrigley, the well-known agent. Since the meeting of the Council above referred to, the Sub-Committee have decided on accepting Mr. Fox's terms; and the Town Clerk has requested him to forward the indemnity he wished them to give before he would impart the information he professes to have in his possession.

GAS APPLIANCES AT THE BRUSSELS EXHIBITION.

Our readers are doubtless aware that there is at present open in Brussels an international scientific and industrial exhibition, the outcome of a movement set on foot by M. Léon Somzée, a well-known Civil Engineer of that city, who, if we remember rightly, furnished the plans in accordance with which the municipal gas-works were constructed. The scheme had the support of the Government; and M. Somzée was appointed President of the Executive Committee. The initiation of the project was briefly noticed in the JOURNAL early last year; it being at the same time stated that two classes of the exhibits would embrace appliances connected with the gas industry. The arrangements for the English Section were entrusted to the able hands of Mr. Lee-Bapty; and it is gratifying to record that this was the first portion of the exhibition ready for inspection—the Belgian and French Sections, curiously enough, being most in arrear. It was opened by His Majesty the King of the Belgians on the 7th ult., with a gold key presented to him by the English Commission, and bearing an appropriate inscription. After considerable delay, the other sections have been completed; and the exhibition is now in perfect working order. This fact was testified to by the Inspector-General (M. Cornely) at a banquet given last Tuesday evening to all the chiefs of departments. Our Brussels Correspondent has forwarded to us a few general notes on those exhibits with which our readers are especially concerned; and their substance is given below. He remarks that, although the collection is not very large, the articles shown deserve a passing notice.

Beginning with the English Section, the first thing to call for remark is the excellent collection of lamps shown by the Wenham Company. They are of all sizes and kinds, suitable for workshops, offices, &c.; some being of very elegant design. A particularly interesting exhibit by this Company is their ventilating lamp (very artistically fitted) for concert-rooms and similar places of entertainment. The Wenham lamp has made great headway in Brussels—in fact, all over Belgium; there being at present about 5000 of these appliances in use in the kingdom. The Fourness Company also have a good display of lamps constructed on their system. There is no specially novel feature in them to call for notice; but all the samples exhibited are well made and in a variety of designs. Mr. J. Greenall, of Manchester, shows the Marsh light; and, as being intimately connected with gas lighting, there is a stand of the Stott regulators, now so familiar at all exhibitions. Passing on to the use of gas for heating and cooking purposes, Messrs. C. Wilson and Sons, of Leeds, have a thoroughly representative display of appliances. One exhibit is specially attractive. It is a fireplace which at first sight appears to be constructed of beautiful black marble, but is, in reality, only cast iron, painted in imitation, and the colours subsequently burnt in, after the manner of pottery. The illusion is perfect. There is also to be seen a small appliance for heating the air of a room. It is readily attachable to an ordinary gas-bracket, and will warm an apartment without giving off any odour or smoke. The stoves constructed on the principle of Mr. Lewis W. Leeds, by which the heat is radiated downwards so as to warm the floor and lower parts of a room, are particularly interesting features of the collection. The radiation is effected by means of a slab of asbestos, perforated with very small holes, suspended above the row of gas-jets, the heat from which it absorbs and throws back, through the opening in the front of the stove, into the room; the downward course of the heat being facilitated by means of an inclined sheet of glass placed in front of the stove.* The mention of asbestos leads the mind to refractory materials generally, several samples of which are on view. Gas-retorts and fire-bricks of various kinds are shown by the Silica Fire-Brick Company, the Glenboig Union Fire-Clay Company, and the Lowood Ganister Brick Company.

In the Belgian Section, the house of Firmin Mignot, of Brussels, exhibit several gas-stoves on M. Wybauw's system. This gentleman (who until lately filled the position of Distributing Engineer in the Brussels Municipal Gas Department), it may be remembered, gained with this stove the prize of 6000 frs. in the competition of gas-heating appliances which took place in that city last year. The stove was described and illustrated in the JOURNAL for May 17, 1887 (p. 900). Like that of Mr. Leeds, it radiates the heat downwards by means of a reflector placed above the gas-flame; and although, at the time of lighting up, almost the whole of the heat is thrown into the chimney, the subsequent effect is the closing of an automatic valve whereby the products of combustion are made to traverse a number of pipes placed below the reflector, so that not more than 16 per cent. of the original heat goes into the chimney. Another stove which gained a prize at the above-mentioned competition was that of M. Wobbe. This appliance, which has lately come greatly into use in Brussels, is shown in various sizes by the maker, M. Blind. M. Vanderborcht has an excellent display of gas kitcheners, roasters, and bath-heaters. A gas-oven specially suitable for pastrycooks is shown by M. Van Leynsele, who has succeeded in constructing an appliance which works very efficiently, and utilizes a considerable portion of the heat produced. The oven consists of two parts, superposed. The lower part is heated by a central ring and two side rows of gas-jets. The products of combustion circulate in wrought-iron pipes, and heat the upper chamber of the oven before passing away into the chimney. M. Van Leynsele, who is himself a pastrycook, has his oven in operation at the exhibition.

* The stove was described by Mr. Leeds, and some particulars given as to its working, in the paper read by him at the recent meeting of The Gas Institute, and published in the JOURNAL last week.

The use of gas for motive power is illustrated by gas-engines exhibited by MM. Bruss, Sombart, et Cie., of Magdeburg; as well as by the Bentz, Otto, and Körting engines—all well-known motors. A Liège firm exhibit a double-cylinder Otto gas-engine of 25-horse power, which runs with remarkable steadiness. Mr. H. Wilford shows a Körting engine adapted to meet the case of the user being without a supply of gas. A small appliance attached to the side of the cylinder generates petroleum vapour which is employed instead of gas to drive the engine.

Among the other exhibits connected with the gas industry may be mentioned a few dry gas-meters on a new system, shown by M. Emile Haas, of Mayence; also a collection of meters (among them being samples of the meters in cast-iron cases supplied to the Rio de Janeiro Gas Company) by MM. Bienvenu et Serret, of Brussels. The General Gas-Meter Company of that city show an assortment of gas and water meters; among the former being several constructed on the double-index principle of M. Wybauw. The testing of the illuminating power of gas is illustrated by one of Herr Elster's photometers, fitted complete with standard candle, inclined mirror for measuring the intensity of inverted flames and electric lights, and all the necessary adjuncts. This instrument was described and illustrated in the JOURNAL for Aug. 30, 1887.

It only remains to say that the lighting of the building and grounds is partly by gas and partly by electricity—four Companies being engaged in the supply of the latter; and that the President of the Executive Committee has put up several gas-lamps on his system by way of competing with the electric lights.

LONDON WATER SUPPLY.*

MR. SCRATCHLEY has done well in reviving the excellent handbook in which the late Sir Francis Bolton described the system of the Metropolitan Water Supply. Published at an absurdly cheap price in connection with the International Health Exhibition of 1884, the book was immediately bought up, and practically disappeared from general circulation. We can readily believe the statement of the publishers that there has been a considerable demand for so useful and unique a treatise. The book being out of print, the opportunity has presented itself for remodelling the entire work, and giving it a more perfect development. It is to be regretted that Sir Francis Bolton has not lived to carry on the literary enterprise which he so happily commenced, and for which he was so specially adapted. But it cannot be said that the work has suffered by the transfer which death has rendered necessary. Mr. Scratchley, as it fortunately happens, was closely associated with Sir Francis in the preparation of the first edition; and he has therefore been able to gather up the broken thread with peculiar facility. A comparison with the former volume shows many improvements, both in the matter itself, and in the general arrangement. The basis remains; but the superstructure is enlarged, and rendered more symmetrical. The book is one-third larger than before—giving space for fresh materials; while the older portions have been in many cases so carefully re-written as to render them almost new. The excellent maps which characterized the first issue have been retained, and have received the necessary corrections, so as to show the extension of the supply and the spread of the constant service. Mr. Alfred Lass's elaborate tables re-appear, brought down to the latest available period, giving a complete view of the financial position with respect to the several undertakings.

The most distinctly novel feature in the present edition is to be found in that part which treats of the law relating to water companies. Mr. Scratchley's legal training here renders him signal service, and enables him to produce a really valuable compendium of the leading legal decisions affecting the relations between the Companies and the consumers. We might, perhaps, venture to differ a little from Mr. Scratchley when he states as a matter of fact that, after the final settlement of the Dobbs case, "water-rates were in numerous cases still assessed on a higher scale than that fixed by the House of Lords." His contention appears to be that "net annual value," as decided in the Dobbs dispute, was equivalent to "rateable value." It is certain that the Companies did not so understand it; and took enormous pains to calculate the annual value according to the terms laid down by the Law Lords. Afterwards came the Water-Rate Definition Act, which, in a most arbitrary and illogical manner, declared that one thing should henceforth mean another—viz., that "annual value" should mean "rateable value." Mr. Scratchley is perfectly right when he says that, "although the effect of the decision in the Dobbs case has been made statutory law by the Water-Rate Definition Act, 1885, the operation of that Act is limited to the area enclosed by the Valuation of Property (Metropolis) Act, 1869; and consequently Dobbs's case, and not the statute of 1885, governs all districts to which the Act of 1869 does not apply." We are disposed to think that there is a yet further distinction to be drawn between the decision in the Dobbs case and the law established by the Definition Act. But if the history of this question were traced back to the beginning, we believe it would be found that the London Water Companies were perfectly justified in their original mode of charge. We commend this research to Mr. Scratchley, though unfortunately the result would come too late to help the cause of the Water Companies, who suddenly found themselves damaged by the very authority on which they were supposed to rest.

* "London Water Supply." By the late Colonel Sir Francis Bolton, C.E. New Edition; revised and enlarged, by Philip A. Scratchley, M.A., of the Inner Temple, Barrister-at-Law, Assoc. Inst., C.E., &c. London: William Clowes and Sons; 1888.

Following his introductory observations on the state of the law, Mr. Scratchley gives a digest of the leading decisions of the Courts as affecting Water Companies generally. This is exceedingly well done; and the perspicuous manner in which the whole is arranged, renders it peculiarly easy for reference. We have here a number of notable cases, and others not so famous. Some of the decisions are curious; and others so highly technical as to surpass ordinary considerations. Among the oddities, though strictly just, we find that "a company is not responsible for an assault committed by a broker or his assistant when executing a distress-warrant to recover arrears of water-rate." This view of the law exonerated the West Middlesex Company when a broker's-man knocked a defaulting consumer through a glass door. There is also the luminous decision which declared, to the detriment of the Liskeard Water Company, that a workhouse was a "dwelling-house," and the inmates "one family." Whether a warehouse is a dwelling-house was not settled by the judgment in the appeal case of *Cooke, Sons, & Co. v. The New River Company*. Mr. Justice Kekewich, in the lower Court, held that the warehouse premises in this case were not a "dwelling-house;" but the judgment pronounced in the Court of Appeal was given irrespective of that point. The law which regulates the supply of water will doubtless continue to furnish fresh questions for magistrates as well as judges. Perhaps in due time, if the deep well which the Commissioners of Sewers are endeavouring to sink in Aldgate becomes an accomplished fact, litigation will arise as to the right of the Commissioners to supply water in the district of the New River Company. In respect to the Cooke case, should the County Council which is to rule over London obtain possession of the Metropolitan Water Supply, it will be interesting to observe how the successors of the Water Companies will deal with the assessment of colossal and highly-rented warehouses.

It would be a pleasant task to travel through some of the lighter chapters in Mr. Scratchley's book; but we must not omit to mention that towards the close of the work, the general statutes relating to water-works [companies are recited at great length, mostly *in extenso*. The historical portions of the book are very readable, and carry us back to times when the water supply of London existed under entirely different conditions from those which now prevail. The growth of the Metropolitan population, and the modern system of drainage, have necessitated changes in the system of supply for which our forefathers were utterly unprepared. In the reign of Henry II., Fitz-Stephen wrote, saying: "Round the City again, and towards the north, arise certain excellent springs at a small distance, whose waters are sweet, salubrious, and clear." Among these there is mention made of Holywell, Clerkenwell, and St. Clement's well, as held in special esteem, "being much the best frequented both by scholars from the schools and youth from the City, when on a summer's evening they are disposed to take an airing." But in the reign of Henry III. "the citizens," it is said, "were forced to seek sweet waters abroad," and for this purpose went as far as "the town of Tyburn," whence the water was conveyed by pipes of lead into the City. In course of time water companies were established, taking their supply from the tidal portion of the Thames, and sending the water to the consumer with scarcely any attempt at filtration. At length there arose a vigorous remonstrance concerning the impurity of the supply. This became particularly marked in 1827; but it was not until twenty years later that the Thames Companies began to remove their intakes up the stream, so as to reach the non-tidal portion. In 1852 came the first Metropolis Water Act, under which the Companies worked so loyally that the General Board of Health, in a report laid before Parliament in 1856, stated: "The new works have not in fact been limited to what a bare compliance with the Act of 1852 would have fulfilled; measures have been adopted for the general improvement of the supplies, which evince a proper anxiety on the part of the Companies in the discharge of the duties of their position towards the public." By that Act it was required that the intakes on the Thames should be above Teddington, and that every Company should "effectually filter all water supplied by them within the Metropolis for domestic use," before the same passed into the pipes for distribution. In 1871 came the present Metropolis Water Act, amending the Act of 1852, and requiring the appointment of a Water Examiner—a post occupied in the first instance by Sir Francis Bolton, at whose death the office was conferred on Major-General A. de Courcy Scott.

A complete history of the London Water Supply would fill volumes; but Mr. Scratchley has compressed into reasonable space an immense amount of information, both in reference to the past and the present, such as will render his book an exceedingly useful and acceptable guide to all who wish to know the leading facts connected with this important and much debated subject. The work is written impartially; and it is to be hoped it will be carefully read by all who seek to form an opinion on the important topic to which it relates. To shareholders and householders the book will be of value for many practical purposes. Should the work pass into another edition—an event which is sufficiently probable—no doubt Mr. Scratchley will still further improve it; but, taking it as it is, we can with justice commend it as an admirable and useful treatise.

The guarantee fund in connection with the proposed display of gas appliances at the Paris Exhibition next year, to which reference has already been made in our columns, now amounts to 249,195 frs. (49968).

Notes.

AN AMERICAN PHOTOMETRICAL STANDARD.

In a description of a photometer designed by the United Gas Improvement Company of America, and recently published in the *Progressive Age*, mention is made of the Edgerton or Mobile standard of light. This consists simply of a standard Sugg "D" Argand burner, with its chimney surrounded by a close-fitting opaque cylinder, usually of brass. In this shield is a horizontal slot, the position and dimensions of which are determined by experiment to coincide with the portion of the gas-flame which is least subject to variation. It is claimed that extensive experiment in this direction has failed to show any practical variation in the amount of light radiated through the slot, when the variation in the illuminating power of the gas did not exceed three candles. The ratio between the Edgerton standard and the standard candle is not stated; but it is apparently of considerably greater brilliancy, since it is advanced that "the object in using this standard is to avoid the extreme liability to err when the candles and gas are compared direct, on account of their large difference in luminosity, which forces the screen to the far end of the bar, where a small motion considerably affects the candle power." It is admitted that the principle of the Edgerton standard is identical with the Methven standard, which must have suggested it; but "the horizontal slot is believed to give more uniform results than the vertical slot of the Methven." No evidence is offered in support of this statement; so that the supposed superiority of the Edgerton or Mobile standard remains questionable. The rest of the photometer is merely a slight modification of the ordinary open-bar instrument familiar in England.

THE OSCILLATION OF CHIMNEYS.

The extent to which chimneys oscillate in gales of wind is always an interesting topic with constructors. In the Memoirs of the French Civil Engineers' Society particulars are published of the recorded oscillations of a chimney-stack 35 metres (115 feet) high, and 1.22 metres (4 feet) exterior diameter at the top, erected near Marseilles. During a great storm, it was ascertained, by observations of the shadow of the chimney, that it oscillated at times as much as half a metre. It was further remarked that, when once set in motion by a violent gust of wind, the chimney rocked backwards and forwards four or five times before coming to rest again. M. Burg observes that the overthrow of the chimney might be expected if the impact of any further impulse should coincide in direction and period with one of these oscillations. This would explain the destruction of many a chimney apparently erected in accordance with sound principles of stability. The *Oesterreichische Zeitschrift für Berg und Hüttenwesen* adds to this statement the qualification that, in the case of a chimney near Vienna, 50 metres (164 feet) high, and built in the concentric rings of brickwork with an inside diameter at the top of 2 metres, which stands in a very exposed situation, the oscillations during severe storms were most carefully and repeatedly measured with a theodolite, and found not to exceed 16 centimetres (6½ inches) in the whole length.

AN AQUA-AMMONIA MOTOR.

Professor George Forbes referred in a recent number of *Industries* to the Campbell aqua-ammonia engine, which he saw on his late visit to the United States. This invention is described as one of the latest attempts to utilize, in the production of motive energy, the vapour of a liquid more volatile than water. In this device an ordinary steam-boiler and engine are used; but ammonia is added to the water in the boiler, and is vaporized when heat is applied. The ammonia vapour is then superheated, and passed into the cylinder, where it works expansively. It then goes into the exhaust, and is afterwards condensed and reabsorbed by water and finally returned to the boiler. The details of the apparatus by means of which the principle is carried out, vary in different examples; but in the general way the process is conducted as follows:—The ammoniacal vapour, on leaving the boiler where it is generated, passes into a reservoir half filled with a weak solution of ammonia in water. The partial absorption of ammonia produces heat, which superheats the ammonia vapour as it passes into the engine cylinder. A pipe leads from the lower level of the boiler to the exhaust pipe, and throws a spray of water on the ammonia in the direction of the exhaust. The heat of this water has been partially used up for warming the feed water, and the spray is considerably cooled when it reaches the exhaust ammonia vapour, which it partially absorbs. This partial absorption, however, creates heat; and this again checks the process of absorption, and would create back pressure if means were not used to prevent it. Accordingly, the vapour and water pass together from the exhaust-pipe into a so-called absorber, which consists of a long horizontal vessel full of horizontal tubes; the rest of the space being occupied by circulating condensing water. The water passes through one-half of the tubes (those which are at the top of the vessel), and falls through the vapour partially cooled, absorbing more vapour; it then returns through the lower tubes, and again falling through the vapour absorbs some more. The vapour and water next pass through a pipe to the bottom of a condenser half full of liquid, and partially filled with tubes through which the circulating water passes. By the time the vapour has risen through this water it is completely absorbed. The solution is afterwards pumped into the boiler. Professor Forbes says that engines upon this principle work well

in practice. The leakage of ammonia from a 105-horse power engine is not appreciable. No lubrication for the cylinder is required. Professor Forbes made special tests for fuel economy with a 60-horse power engine, with and without ammonia. He found that the engine, which required a consumption of 6·2 lbs. of fuel per horse power when working with steam alone, did the same work with 2·6 lbs. of fuel when worked with ammonia. The saving was thus about 60 per cent.

Communicated Article.

OXYGEN PURIFICATION.

By H. LEICESTER GREVILLE, F.I.C., F.C.S.,
Chemist to the Commercial Gas Company.

I read with much interest Mr. Valon's paper on "The Use of Oxygen in the Purification of Coal Gas," and regretted that circumstances prevented my being present at the time it was engaging the attention of the members of The Gas Institute at the recent meeting. There is, however, some consolation to be derived from the fact that more is probably to be learnt from the calm perusal of a paper, and its attendant discussion, in the quietude of one's own study, than in any other way. It is more or less difficult during the reading of a paper to thoroughly appreciate all its good points or to criticize all its omissions. The time for discussion is generally limited, and those who are the most fluent in speech and the readiest in debate secure the lead; and, however valuable the discussion may be, it is seldom sufficiently exhaustive. Any question of real importance and novelty merits more consideration than it usually receives on the mere reading of a paper; and I therefore send a few remarks to the JOURNAL, with a hope of contributing something useful to the elucidation of the special subject of the purification of coal gas by oxygen.

There is no doubt that the germ of this system is the old practice of the revivification of oxide *in situ* by the limited use of air—a practice which, abandoned for a time, has again been adopted more latterly in various places, but with varied opinions as to its success. Concerning the broad points of saving in labour and increased duty of material by the use of this method, there can be little doubt; but the debatable issue is the effect on the lighting power of the gas. Some experimenters who have used air (among whom is Mr. Valon) claim a *decrease* in light; others (as Mr. Septimus Penny) an *increase*. In the discussion on Mr. Valon's paper, no one claimed an increase of light consequent on the use of air. Messrs. Botley, Denny Lane, and Norton H. Humphrys stated that they did not find any depreciation of illuminating power consequent on its use; while Messrs. Newbigging, Anderson, and Frank Livesey inferred that the use of air would inevitably lead to deterioration in the lighting value of the gas. I believe I am correct in stating that Mr. Methven is still using air, and finds no depreciation in the illuminating value of the gas. The subject is therefore still a debatable one. My own impression is that the question can only be settled by experience, and that the diluent effect upon lighting power known to be exercised by the admixture of nitrogen with ordinary gas cannot be taken as a quantitative basis for estimating what would be the effect of introducing nitrogen in the ordinary process of gas manufacture. The lighting power of gas is, to a large extent, due to many substances—such as benzole vapour, naphthalene, &c.—which are partially retained by the gas, and partially separated with the tar during the process of condensation. Air introduced at a suitable point in the manufacture, where it would become more or less impregnated with a portion of the benzole and naphthalene, which would otherwise be retained by the tar, would not be likely theoretically to reduce the illuminating power of the gas to such an extent as the direct admixture of nitrogen with the purified gas. There is an additional point tending to mitigate the reduction in illuminating power which would theoretically attend the use of air, and concerning which I will quote from an article of mine, published in the JOURNAL for Nov. 1, 1887, on "The Revivification of Oxide *in Situ*:" "There is the question of heat developed in the purifier preventing the undue deposition of condensable hydrocarbons, and thereby mitigating the loss of illuminating value, which is a common experience of gas managers as a result of over-condensation. This point is of more especial importance in cases such as occur in local gas-works where the purifiers are generally in an exposed position, and where (especially in the winter months) the lowering of the temperature of the gas must be excessive."

Referring to the actual details of Mr. Valon's paper, I notice in the first place that the area of the purifiers, in proportion to the make of gas, was (as pointed out by Mr. Frank Livesey) at least five times as great as is generally employed; and this, it is almost needless to state, would place the purification of the gas at a great advantage over the usual practical conditions in use at the majority of works. In the second place, although in the experiment on the use of oxide, details are given as to the initial light (14·67 candles), and the light with 0·1 per cent. by volume of oxygen per 100 grains of sulphuretted hydrogen per 100 cubic feet (15·46 candles), showing an increase of 0·79 candle, yet in the case of the use of lime no comparative results are given. We learn that, with the use of the same proportion of oxygen as before, the illuminating power of the gas was 16·5 candles. Now this apparent increase in illuminating value was not obtained merely by the use of oxygen; and as no

comparative figures are given as to the normal light which would be obtained where lime was used as a purifying agent in the absence of oxygen, a theoretical estimate must be made. The carbonic acid present at the inlet of the lime purifiers was 1·26. Taking as a minimum basis that 1 per cent. of carbonic acid reduces the light by 6 per cent. on an Argand burner, the 1·26 would be equal to 7·6 per cent.—say, roughly, 8 per cent. This would reduce the 16·5 to 15·2 candles. The initial light of the gas purified by oxide only was given at 14·67. The gain, therefore, due to the oxygen process where lime was employed, was 15·20 - 14·67 = 0·53 candle—less than that claimed for the use of oxide. I cannot understand this apparent discrepancy, and cannot offer even any theoretical explanation of it.

Turning to the action of the lime *quo ad* purification, the effect of the addition of oxygen is very remarkable; and the results obtained by Mr. Valon are of very great interest. Even allowing for the favourable effect of a large area of material in comparison to the make of gas, the recorded results are remarkable in two details—viz., (1) That the carbonic acid and sulphuretted hydrogen should have kept so much on a level with each other. (2) That it was possible to effect the complete purification of the gas, removing thoroughly carbonated lime, and yet keeping the sulphur compounds down to from 6 to 8 grains. I have not had the opportunity of examining any of the spent lime; and it is almost needless to say that, for the examination to be of real value, the sample should be fresh from the purifier, and shielded from the action of air prior to testing. It may, however, be of some value to speculate on the nature of the chemical actions at work during the use of lime and oxygen in purification, more especially as very little light was thrown on this branch of the subject when Mr. Valon's paper was read. The actions which take place may be, and doubtless are, more or less complex; but some clue to their nature may be gained by considering the various reactions as divided into separate stages. It is a well known fact that lime exposed to the action of sulphuretted hydrogen, in the presence of moisture, forms calcium sulphhydrate (CaSH_2S); and we may assume that this compound is actually formed in the purifiers when the sulphuretted hydrogen in the gas is absorbed by lime. It is also known that the ordinary product of the action of *cold gas* on *cold lime* does not form a product active in absorbing carbon disulphide. I have repeatedly made the following experiment:—Gas containing sulphuretted hydrogen, but free from carbonic acid, was passed into slaked lime in a small experimental purifier, until the sulphuretted hydrogen showed at the outlet. The product was absolutely inactive on sulphur compounds. The lime was now turned out of the vessel, and exposed to the air in a heap, when it heated, turned yellowish green in colour, and when replaced in the purifier was found to have developed a remarkable energy in absorbing carbon disulphide. Chemically, the raw sulphided product gave evidence of containing calcium sulphhydrate, as its solution in water gave a black precipitate with a soluble salt of lead. The partially oxidized product gave a totally different reaction—affording a yellow solution, and a red precipitate with a lead salt; giving, in fact, evidence that calcium sulphhydrate had disappeared, and had been replaced by one of the higher calcium sulphides—I have much reason to believe by calcium pentasulphide (CaS_5). The fact of the higher calcium sulphides uniting with carbon disulphide has not, to my knowledge, been brought before the notice of the gas community; but I had some time back observed the fact, and have recently found a record of its being known in 1875. In the abstract of the session of the French Academy for that year, the following occurs (I give a free translation):—"M. Gélis has observed that sodium bisulphide (Na_2S_2) unites directly, and with great evolution of heat, with carbon disulphide. The salt produced— $\text{Na}_2\text{S}_2\text{CS}_2$ —belongs to a new series of sulphocarbonates. It is comparatively soluble in water and alcohol, and yields no sulphur to carbon disulphide. The common sulphocarbonate— $\text{Na}_2\text{S}\cdot\text{CS}_2$ —as is known, is with difficulty soluble in alcohol. It can also be prepared by dissolving sulphur in the sulphocarbonate, $\text{Na}_2\text{S}\cdot\text{CS}_2$ which takes up exactly one atom of the sulphur. When carbon bisulphide acts on higher sulphides—sodium tria and penta sulphides—the above salt is produced, and the excess of sulphur is liberated in the free state."

I can so far corroborate the statements of M. Gélis that, when experimenting on the subject some years back, I found, on agitating a solution of calcium pentasulphide with excess of carbon disulphide, the solution at first became turbid from separation of sulphur, and finally cleared from the solution of the sulphur in the liquid disulphide. Also, on evaporating the disulphide solution, I obtained free sulphur equal to three-fifths of the total amount originally present. This exactly conforms to the equation—

This is an analogous reaction to that shown by M. Gélis operating on sodium trisulphide. These facts undoubtedly bear on the question of the action of oxygen on lime in the presence of sulphuretted hydrogen, in reducing the sulphur compounds in the gas, and in explaining the presence of free sulphur in the spent lime.

Let us assume that the first action of the sulphuretted hydrogen upon the lime is as follows:—

in which calcium sulphhydrate is formed. The action of oxygen on this might be as follows:—

in which five molecules of calcium sulphhydrate become converted

into two molecules of calcium pentasulphide, and three of calcium hydrate.

The practical effect of this would be: (1) That the product would develop a power of absorbing carbon disulphide. (2) That, owing to the fact that calcium hydrate would be formed, there would be an increased purifying capacity. The fact of the spent lime containing free sulphur might be accounted for in three ways. First, as a reaction between carbon disulphide and calcium pentasulphide:

Second, as a product of the continued action of oxygen on calcium pentasulphide, in which, by equation, 1, or 2, or 3, calcium sulphite, sulphate, or thiosulphate might be formed—

Third, as a product of the reaction between calcium pentasulphide and carbonic acid—

If the reactions I have shown as possible represent, in the main, what occurs when oxygen and sulphuretted hydrogen react on lime, it is not difficult to understand how the purification from sulphur compounds takes place, and also the presence of free sulphur in the spent material. The spent product should consist theoretically of calcium carbonate, sulphate, thiosulphate, and perhaps a little sulphite intermixed with more or less free sulphur. Such a mixture, subjected to heat in a closed vessel, would no doubt give off sulphur in a form in which it could be collected and utilized.

One point in connection with Mr. Valon's results on sulphur compounds has yet to be explained. It is well known that carbonic acid decomposes the ordinary combination of carbon disulphide and sulphided lime, driving the "sulphur" forward; and that in a rotation of lime vessels the "sulphur" at the outlet can only be kept down by changing at a period when the first or "A," vessel is incompletely carbonated. This is explained by the decomposition of the calcium sulphocarbonate (formed by the combination of carbon disulphide and calcium sulphide) as follows:—

in which the products are calcium carbonate, carbon disulphide, and sulphuretted hydrogen. As far as Mr. Valon's experiments on the oxygen system of lime purification extend, it appears that the lime in the "A" vessel was thoroughly carbonated, while the gas at the outlet of "B" was still low in "sulphur." If this really represents a normal action which would be maintained by a more extended trial, it must mean that the compound formed between the lime and the carbon disulphide must be capable of such active oxidation that even the combined bisulphide is oxidized, and retained in a fixed condition by the lime.

With regard to the cost of oxygen purification as compared with the ordinary system, and with that in which air is employed, that is a practical question of which gas engineers will no doubt be able to form a competent opinion; but I consider, before the subject can be really settled, we need to have a larger experience as to the effect of the use of air on the lighting power of the gas. Possibly Mr. Methven and others who have had experience in the matter, will give us the benefit of their conclusions.

GAS v. ELECTRIC LIGHTING IN BELGIUM.—We learn from our Brussels Correspondent that one of the most extensive cafés in Belgium—the Café du Phare at Liège—which since its opening has been illuminated by incandescent electric lamps, is now lighted by gas. The original installation was put in by M. M. Gerard et Cie, of Brussels; but the proprietor of the café found the lighting insufficient, and brought an action against the Société Electrique for damages. The whole of the original lighting plant has been removed, and is now for sale; a number of the Wenham Company's "Electric" gas-lamps being employed instead. This Company appear to be specially successful at café lighting; for their lamps have just been adopted in the Café des Trois Suisses in Antwerp, *vice* the abandoned electric lights supplied to this establishment by Messrs. Siemens and Halske.

CORPORATION TRADING.—In last Wednesday's *Money*, allusion was made to the subject of Corporation trading, in continuation of some observations made about a year ago in an article (reproduced in our columns) dealing with the manner in which corporations spend the enormous sums they borrow upon the security of the local rates. Our financial contemporary remarks: "So long as a corporation expends borrowed money in improving a town as a town, and in directions which distinctly tend to increase the rateable value, we can only discuss, as we did in our previous article upon this subject, the too often carelessness and extravagant manner in which the funds are frittered away. But when large sums are borrowed for the purpose of constructing docks or canals, the matter assumes a different aspect. At the same time it is not difficult to understand the process of reasoning by which worthy aldermen and town councillors justify their action in embarking in such enterprises. They evidently consider it to be their duty to spend money in any works which may ultimately bring trade to the town, and possibly make a great addition to its rateable value. But they entirely overlook an old proverb, which bids the shoe-maker never to go beyond his last; or, in other words, not to interfere in a business which he does not understand. Their business is to carry out sanitary and similar undertakings, leaving risky commercial enterprises to private individuals or to public companies."

Technical Record.

SOCIÉTÉ TECHNIQUE DU GAZ EN FRANCE.

THE PAPERS AT THE BOULOGNE CONGRESS.

In the JOURNAL for the 10th inst., we noticed briefly, from the abstracts in the *Journal des Usines à Gaz*, some of the papers read at the recent meeting of the Société Technique at Boulogne. We now deal with the remainder.

M. Salanson presented a communication on the subject of the regulation of pressure at the works, and on the flow of gas in pipes. He first of all laid down the following rule:—Given a certain condition of the orifices at which the consumption of gas takes place, the pressure at each point of a horizontal network of mains is proportionate to the pressure at which the gas is sent from the works. The author applied this rule in various ways before passing on to deal with the subject of the flow of gas in mains. Calling "the ratio of charge" at a given point in the canalization the ratio between the pressure existing at a particular moment at this spot, corrected by the difference in level as compared with the point of emission, and also with the initial pressure, the author established, under certain circumstances, the following principles:—(1) The "ratio of charge" at each point of the mains is constant for a like condition of the orifices at which consumption takes place. (2) For a given condition of these orifices, the ratio of consumption at each to the total consumption is constant. An examination of the conditions under which the first rule was applicable showed that for mains having a diameter of more than 16 inches, it could be applied strictly; but that for pipes of smaller calibre it could not, although it is sufficiently exact so long as the consumption is not doubled. In the case of lead pipes less than 2 inches in diameter, the loss of charge may be regarded as proportionate to the average rate of flow. In cast-iron pipes of from 2 to 20 inches in diameter, it is in proportion to M. Arson's two-term formula; while in those of larger diameters it is proportionate to the square of the speed. For the same pipe two definite speeds may be considered—viz., a higher speed, beyond which the loss of head is proportionate to its square; and a lower speed, beyond which the loss is in proportion to the simple speed. Between these limits, M. Arson's formula must be employed. Except, however, in the case of pipes of large size (say, from 52 inches upwards in diameter), the limits considered are not generally met with in connection with gas supply.

In a paper on the subject of detecting leakages from gas-mains, M. Schauflier described some experiments with the system introduced by Dr. Bunte of testing with chloride of palladium, which was noticed in the JOURNAL for Jan. 12, 1886 (p. 69). Before putting the plan in operation on a rather extensive scale, M. Schauflier was led to make a few experiments in the laboratory, with the view of ascertaining the best proportions of the constituent elements of the testing liquid to employ, so as to attain the highest degree of sensitiveness. He decided upon the following formula:—Chloride of palladium, 3.75 grammes; chloride of gold, 1.25 grammes; dissolved in a litre of distilled water. Test-papers steeped in this liquid were placed in tubes about 3 feet high fixed over a length of three miles of main—something like 2500 tests being made. The result was the discovery of leakage to the extent of 33.6 cubic metres (about 1200 cubic feet) per 24 hours; or for a year, 12,264 cubic metres (433,000 cubic feet). Reckoning this at 10c. per cubic metre, the loss was put at 1226 frs. The expense of testing being about 250 frs., the net benefit resulting in the first year was 976 frs., or close upon £40. It may be added that a pint of the liquid prepared according to the formula costs about 9s., and will steep enough filter-paper for 8000 to 11,000 tests.

M. Melon, in an interesting communication, indicated the various purposes for which gas-engines may be employed in gas-works; submitting a number of figures showing the advantages to be gained by utilizing gas as the motive power for driving the exhausters, scrubbers, pumps, coke-breakers, &c. He took two works where the production of gas is about equal, but where steam-engines are used in one, and gas-engines in the other. In the former, the cost was 3 fr. 84c., and in the latter 3 fr. 90c. per 1000 cubic metres of gas made; being equal to 1.03d. and 1.05d. per 1000 cubic feet. In the works where steam was employed, breeze was the only fuel used, and its cost was put at about 1d. per bushel; the gas consumed in the gas-engines being reckoned at 1s. 1½d. per 1000 cubic feet. The difference is not very considerable; and therefore the author left his hearers to draw from his figures whatever conclusions they considered to be applicable to the special conditions of their own works.

In a short paper by M. Weil-Goetz, the important subject of the treatment of spent purifying materials, for the recovery therefrom of sulphate of ammonia, was dealt with. The process described by the author is based on the two following principles:—(1) In systematic lixiviation, the solvent liquid increases in weight in proportion as it becomes charged with salt in solution; (2) in two vessels in communication, a column of liquid of low density is capable of balancing, and even of displacing, a shorter column of a liquid of higher density. The lixiviating apparatus is composed of a series of four vats, each furnished with a false bottom of wicker-work covered with canvas such as is used for packing, on which the material to be dealt with is placed. The vats are connected by pipes provided with taps and plugs, so that a systematic circulation of pure water can be kept up until the material has been thoroughly exhausted. Each ton of spent material produces from 20 to 24 cwt. of lye of the strength of 12° Beaumé (17° Twaddell),

containing rather more than 2 per cent. of ammonia. The process is by no means expensive. The treatment of 10 tons of spent material required 56 hours' labour, the cost of which was 16 fr. 80c., or 1 fr. 68c. (say 1s. 4d.) per ton. In the past year, with a make of 176½ million cubic feet of gas, the author produced 60 tons of spent material, the treatment of which yielded about 30 cwt. of ammonia, worth £40 a ton, at a cost of £4—leaving a net profit of £36. After lixiviation, the stuff is sold to a manufacturer, who extracts therefrom Prussian blue; paying at the rate of £20 per ton of blue obtained. This yielded a return of £100; bringing up the total receipts to £156—being at the rate of about 18s. per million feet of gas made, and 2½d. per ton of coal carbonized.

M. de Lachomette introduced to the notice of the members a new process for the manufacture of sulphate of ammonia. This paper was regarded as one of the most important submitted to the meeting. The author has devised a simple and economical method for the direct production of sulphate of ammonia by means of the constituent elements of the coal itself. The spent purifying material is roasted in a Michel-Perret oven, which causes it to yield sulphurous acid. This is led into a vat filled with water, into which at the same time is introduced a current of ammonia. The result is the formation of sulphite of ammonia, and, if there is an excess of sulphurous acid, bisulphite of ammonia, which is much more soluble than the preceding. With an excess of ammonia, the bisulphite is afterwards reduced to the state of sulphite, which, being deprived of one of its equivalents of water, is readily transformed into sulphate by simple exposure to the air. In the discussion upon the paper, some doubt was thrown on the statement that the sulphur from the spent material would yield sufficient sulphuric acid to saturate the whole of the ammonia; in other words it was questioned whether sulphur and nitrogen would exist in the coal in suitable proportions to furnish, of themselves, sulphate of ammonia. Opinions will differ on this point, according to the nature of the coal employed. But it may be pointed out that the advantage of the process consists in dispensing with the purchase of sulphuric acid, and in the facility afforded of producing sulphate directly by roasting crude sulphur. In this way all the annoyance caused by the employment of sulphuric acid, which is not always perfectly concentrated, may be avoided.

Several interesting questions were brought before the meeting by M. Chevalet. First of all, he referred to an improved form of the Leroy-Chevalet coke-breaker, by means of which it is claimed that two men are able easily to break from 27½ to 33 bushels of large coke per hour. He next alluded to an apparatus for the production of volatile alkali. He begins by saturating the ammoniacal liquor with lime, in order to decompose the whole of the ammonia; and afterwards distills the decanted liquor. The alkali, on leaving the stills, flows into a cooler; and the dry ammoniacal gas is freed of its empyreumatic oils by being passed into linseed oil or into charcoal filters, before being dissolved in water placed in vats of sheet iron, lead, or stoneware. Another matter, bearing upon the treatment of residuals, was the utilization of ammoniacal liquor for the manufacture of manure. M. Chevalet concentrates his liquor to about 22° Beaumè (say, 56-oz. strength), and then brings it into connection with ordinary commercial superphosphate of lime. The proportions of the two ingredients are regulated by the smell. The manufactured manure should not have the odour of ammonia. The stuff is exposed to the air for about 24 hours, at the end of which period it may be put up in bags or warehoused. Referring to the subject of the value of spent purifying material, M. Chevalet indicated how it might be increased by augmenting the content of nitrogen. He recommended the use of material prepared with sulphite of iron and lime, or Laming material, with white wood sawdust. The last matter touched upon by M. Chevalet was gas analysis. He described a burette which appears to have been constructed on the principle, if it is not actually a reproduction of that of M. Coquillion, which was described and illustrated in the JOURNAL for Jan. 31 last (p. 195).

A communication on the subject of the presence of cyanogen and its compounds in the products of the distillation of coal was presented by M. Pendrié. The author inquired into the reason of the generation of cyanogen and its various combinations in the carbonization of coal; defined the exact quantity and form in which they are met with in the various periods of the gas-manufacturing process; and described, from a practical point of view, the means of transforming them, at trifling cost, into articles of commerce. The conclusions he arrived at may be thus shortly stated: (1) In the process of the distillation of coal there is always formed, at the expense of the ammonia, a certain quantity of cyanogen, which is found in the distillation products in the form of cyanide and sulphocyanide of ammonium. (2) It is in the liquor contained in the hydraulic main that the larger proportion of the cyanide of ammonium is dissolved; and it is there that this compound is found in the greatest state of purity. (3) Only a comparatively small quantity of cyanogen is met with in the purifying material, and then principally in the form of sulphocyanide; in other words, in a very unsuitable form for the preparation of ferro-cyanides. (4) The transformation of the cyanides into ferro-cyanides is effected at small cost. Analyses show that, in order to attain this object, it is advisable to draw off and treat separately the liquor from the hydraulic main, in which there is scarcely any sulphuretted hydrogen, by which means the cost of transport would be diminished, and a purer product be obtainable. (5) Theory shows that it is possible to transform half the nitrogen liberated from coal in the form of ammonia, first into hydro-cyanide, and then into ferro-

cyanide of ammonia—a product of greater value than ammonia for an equal weight of nitrogen. It remains to be ascertained whether or not the practical result of this transformation is such as to allow of the system being profitably worked on a commercial scale.

The last matters to be noticed in connection with the congress relate to the consumption of gas. M. Bouvier presented a short communication on the subject of the light-giving capacity of gas-burners. The author gave, in tabular form, the results of his own experiments, and indicated the best burners and globes to use in order to utilize gas to the best advantage. M. Giroud exhibited the latest model of the Guibout burner, which has already been described in the JOURNAL (*ante*, p. 27). Several of these burners have been fitted up in the new waiting-room at the Western of France Railway Terminus in Paris. He also showed an arrangement of the Delmas burner with flat flame, for the lighting of railway carriages by means of oil gas. M. Pottier sent a "Note" on a new high-power burner, called the "Industrial," which it was stated would give the light of 9·5 candles with a consumption of 1·2 or 1·5 cubic feet of gas, according as the hourly consumption is 15 or 26 cubic feet. There is a certain similarity between the Delmas burner and the Siemens flat-flame burner; also between the "Industrial" and the Schulke. This resemblance did not escape the observation of the members.

In the foregoing abstracts we have merely endeavoured to indicate the nature of the principal communications presented at the congress; reserving for subsequent issues any fuller notice of them that may be considered desirable.

WESTERN (U.S.A.) GAS ASSOCIATION.

To-day we conclude our abstract of the "Official Report," as given in the *American Gaslight Journal*, of the proceedings at the annual meeting of the above Association.

Mr. W. M'DONALD, of Albany, N.Y., contributed a paper bearing the title "The Maximum Service that should be Required from the Various Standard Sizes of Meters." The author directed his remarks more particularly to dry meters. He observed that the real question was not how many lights were to be supplied from the meter, but the speed at which it was to be worked and the quality and temperature of the gas passing through it. A burner may use any quantity from 2 up to 10 cubic feet of gas per hour. He considered the maximum quantity a meter would safely pass was its nominal capacity multiplied by 10, as shown in the following table:—

Size.	Cubic Feet Per Hour.	Revolutions Per Hour.	One Year's Working.	Total Gas.
3 Light . .	30	240	2,102,400	262,800
5 " . .	50	300	2,628,000	438,000
10 " . .	100	400	3,504,000	876,000
20 " . .	200	400	3,504,000	1,752,000
30 " . .	300	360	3,163,000	2,628,000
45 " . .	450	360	3,163,000	3,942,000
60 " . .	600	360	3,163,000	5,256,000
80 " . .	800	350	3,066,000	7,008,000
100 " . .	1000	350	3,066,000	8,760,000

In addition to the quantity of gas passed, he added the number of revolutions per hour, also the number of revolutions and the total gas measured if the meter worked continuously for a year, which he thought gave a fair idea of the durability, or the duty that might be expected to be done before the machine was worn out. He was assuming that the meters would be subjected to no other deteriorating influence than actual wear. This table applied more to the larger sizes than to 3 and 5 light meters. It would be seen that these were figured to work rather slower than the others; but really, on account of the lightness of the work and the shortness of travel, they would bear a considerable increase. If a dry meter was not overworked, he thought it would comfortably bear a pressure as high as a pound per square inch (27 or 28 inches of water). He unhesitatingly asserted that meters were practically accurate, if allowed a fair chance. The three chief things meters had to contend with were impurity in the gas, condensation, and especially temperature. Given a gas free from condensable vapours and sulphurous or acid impurities, kept at a moderate uniform temperature, almost absolute accuracy could be insured. It was not always possible to control all these conditions, but if they received more consideration, meters would work better and last longer.

Replying to questions, Mr. M'Donald said the best locality in a building for the meter was the cellar. The temperature should not fall below 50° or rise above 70°. The effect of cold was to stiffen the moving parts, and he did not object to the use of alcohol for thawing a meter, if properly applied. If the rates per hour quoted in the table were exceeded, no great harm would follow until some of the machinery broke, when the meter would either fail to pass gas, or let it through without being registered. While well-made water gas was not prejudicial to a meter, he had observed that if a meter which had been used for water gas, was taken out and permitted to stand, the diaphragm always hardened, and anything that tended to harden the diaphragm would lead to fast registration.

Mr. H. PRATT, of Chicago, Ill., next read a paper on "Inclined Retorts." After noticing some early endeavours in this direction, he described the system patented by M. Coze, of Rheims, France;*

* See JOURNAL, Vol. XLVII, p. 25.

and then proceeded to give details of a system of inclined retorts designed and erected by himself—the retorts being set at an angle of about 30°. He had constructed a bed of six retorts over a common furnace, each retort being 12 feet long, 13 in. by 24 in. at the upper, and 13 in. by 28 in. at the lower end. Inside the lower end was a stop to keep the coal from slipping down into the cool part close to the mouthpiece. There was no difficulty in getting the charge in fairly level, and if well worked off, it would fall out, on opening the lower lid and removing the stop. If not completely coked, a little assistance with a small iron rod was all that was necessary. The retorts were readily cleaned by loosening both lids, the current of air being adjusted by the bottom lid. The charging apparatus consisted of a travelling-hopper, supported on overhead rails, above the level of the top row of mouthpieces, and having shoots for delivering the coal into each retort as desired. For a series of such benches, a line of rails to carry the hopper could be supported between two rows, and would serve for both. It could be driven by any suitable power, and an elevator used to replenish the hopper.

At the conclusion of the paper, Mr. Walsh remarked that he had visited Rheims, and had seen the system of M. Coze applied to a setting of nine retorts. He was so pleased with it that a similar set for five retorts had been ordered for St. Louis, and had just been completed and started. Mr. Taylor said that the bench mentioned by Mr. Walsh had been at work for seven days when he left. In twenty-four hours it carbonized 9600 lbs. of Youghiogeny gas coal, yielding 48,864 cubic feet of 16 to 20 candle gas, or 5'09 cubic feet per pound. The coke produced was 157 bushels (35 lbs. per bushel), of which quantity 74 bushels, about 47 per cent, were burned in the furnace. This was with 400-lb. charges; but he thought that when in proper operation the bench would take 500-lb. charges. They remained in the retort for five hours; but he expected to be able to work shorter charges. This bench was erected in a separate building, away from the other retorts; and therefore the fuel account was higher. The retorts were 11 ft. by 15 in. by 26 in. He had tried various sizes of coal, and found that egg coal spread best in the retorts. There was a saving in labour, and also in leakage, because the charge was in and the lid closed in two seconds.

Mr. E. LINDSLEY, of Cleveland, Ohio, contributed a paper on "Incandescent Gas-Burners." The incandescent gas-burner had been called into existence, the writer remarked, by the desire to use, if possible, cheap heating gas as an illuminant also. A description of the Welsbach and of the Fahnejelm burner was given; and the author quoted some experiments made by Mr. A. C. Humphreys, of the Welsbach Incandescent Gas Light Company. The following is a summary of the results.

Gas per Hour, Cubic Feet.			Candle Power per Cubic Foot of Gas Used.					
			Burner No. 1.	2.	3.	4.	5.	6.
2.9	..	After 20 Hours' use	10.0	8.0	4.5	9.7	11.7	11.0
3.0	..	" 50 "	8.7	6.0	3.3	6.7	8.0	8.7
3.3	..	" 160 "	7.6	5.7	1.8	7.3	7.3	8.2
3.2	..	" 250 "	6.0	4.7	1.9	6.7	6.0	6.7
3.0	..	" 400 "	6.0	3.3	2.0	5.7	3.0	6.0
3.0	..	" 600 "	6.0	5.1	2.3	5.7	5.0	7.0

The gas consumed for the last test was 20 candle; but the value of that used in the other tests is not given. Burners Nos. 1, 4, and 6 were fitted with the larger mantles, which were said to be of the American type. Nos. 2, 3, and 5 were the smaller mantles of the European type. The former were used with straight chimneys, and the latter with tall ones contracted near the base. No. 3, which gave by far the worst results, is of the variety which yield a white light, and it was selected as the best by several observers. The "European" burners appeared to depreciate by the destruction of the horizontal threads in the mantle at the point of contraction. No. 2 showed a disposition to disintegrate by the force of the explosion that frequently occurs in attempting to light this kind of burner, and during the latter half of the time, it had two or three large holes in it. The American burners would stand reasonable usage without breaking. The practical question was whether the increased duty obtained would offset the additional care required and the increased cost of the burners.

In the course of the subsequent discussion, the President remarked that the experiments quoted had been continued up to 1056 hours' use, at which period the results were as follows:—No. 1, 4 candles; No. 2, 3 candles; No. 3, broken; No. 4, 4.9 candles; No. 5, 3.3 candles; and No. 6, 6.6 candles. It would be seen that the American types were more durable than the foreign. Of course, it would not pay in practice to run the burners beyond the 600 hours. The form of chimney used with the European burner was unsuitable, because it was almost impossible to light it from the top. With the ordinary straight chimney, 7 to 10 inches high, as used with the American burners, there was no difficulty of this kind. There was as much difference between the European and American types of Welsbach burner as between an oil-lamp and a gas-burner. Mr. Egner said he had tested a Fahnejelm burner, and found that 3 cubic feet of coal gas used in an Argand gave as much light as 5 feet of uncarburetted water gas in the Fahnejelm. He was told that this burner would not do for illuminating gas; but he had since seen a much better result with this burner, and the magnesia comb was very cheap—only 14d. Mr. Lindsley said that the difficulty in lighting the Welsbach burner had been partly and perhaps wholly removed.

Mr. J. D. THOMPSON, of St. Louis, Mo., read a paper on "Gas Companies Accounts." He called attention to the importance of knowing exactly what the gas cost in the holder, and also the

cost of each item of expenditure per 1000 cubic feet of gas made and sold. Especially was it necessary, in these days when the patent gas man is about, to know exactly what the manufacturing charges were, and to keep them distinct from the management and other expenses. It was also desirable to observe a strict distinction between revenue expenses for the repair of existing plant, and the cost of new and additional machinery, which was properly chargeable to capital. He was in the habit of working out statistics as above suggested each month; and he exhibited a leaf from his account-book, showing the manner in which the several items were separated. The reason for working out the cost of gas made, and also of that sold was that he considered the difference between these two columns showed the actual loss by leakage in a more comprehensive manner than the usual plan of stating the percentage of unaccounted-for gas. He had now kept these accounts for ten or twelve years; and the value of being able to compare his working each month with corresponding periods was very great, and often led to the detection of weak places that would otherwise pass unheeded. In regard to the keeping of the consumers' ledgers, the system he recommended was a separate ledger account for each customer, appearing in the book in the alphabetical order of streets and house numbers; and each ledger contained space for 1000 accounts—two on each page. With monthly accounts, it would last for a period of three years. A system of journals and cash books is used in connection with the ledgers.

The discussion was opened by Mr. King, who proposed the appointment of a Committee, with Mr. Thompson as Chairman, to report upon and recommend a suitable system of accounts, for use as a standard of comparisons, at the next meeting. The system should be applicable to large and small undertakings alike. This proposition was subsequently adopted and a Committee appointed. In reply to questions, Mr. Thompson said his plan was to compare the make of gas with the actual cash received. Outstanding accounts, as a rule, were not carried forward at all, except in the case of large payments from the city or large consumers. Even the smallest undertaking could well afford the cost of keeping accounts on his system; and where one man had charge of the whole, it was proper to apportion his salary—part to the manufacturing, part to the distribution, and so on. In the case of small pipes replaced by larger, the additional cost only of the latter should be charged to capital account. He did not trouble about the stock of gas in the holders at the end of each month, as it varied but little. The stock of coal was carefully estimated. Mr. Barker said the plan proposed by Mr. Thompson was similar to that adopted by the Massachusetts Gas Commission.

Mr. F. BIERCE, of Memphis, Tenn., read a paper on "Half-Depth Generator Furnaces," a full abstract of which appeared in the JOURNAL for July 17, p. 122, with a summary of the subsequent discussion.

Professor MENDENHALL, President of the Rose Polytechnic Institute, Terre Haute, Ind., delivered a lecture on "Photometrical Standards." Having noticed the present confusion existing on this subject, he proceeded to consider the nature and requisites of a standard—that it should be unrestricted both in respect to time and place, convenient, and readily accessible to all. It was also desirable that the standard should be of the same kind as the thing to be measured. In measuring light, the standard should be a light; but he was beginning to have serious doubts as to the possibility of establishing a standard light, and thought it would be necessary to resort to indirect measurement. Directing attention to the various units of light already proposed, he said that the principal objection to the platinum unit was the great difficulty attending its production—a difficulty so great that it had probably been only produced by one or two men. It not only needed careful manipulation, but was very expensive; and it could not be reduced to terms of other standards at present in use. A table from Wagner's "Chemical Technology"—showing the comparative value of the Carcel, the platinum, the French stearine candle, the Munich stearine candle, the German union candle, and the English sperm candle—was exhibited; and it was pointed out that the various figures did not fit in together within 20 or 25 per cent. Several particulars of these proposed standards, and also of the Hefner-Altenack lamp, were given. Some of the difficulties peculiar to photometrical operations were next reviewed. The article to be measured is uncertain in character and composition, not constant in quantity, and not of any known or definite character. It might be compared to an attempt to measure a sheet of elastic rubber subjected to varying degrees of tension, by means of a yard stick of similar material. One of the first steps towards reliable photometry would be an accurate definition of what light is, and the kind of light to be tested. Referring to the energy of various kinds of illuminants, the Professor stated that if all the heat produced by a stearine candle in the act of burning could be converted into work, 8.77 of such candles would be equivalent to 1-horse power. The spermaceti candle gave a rather lower result—viz., 8.97 of this kind were equal to 1-horse power. A jet of gas consuming 5 cubic feet per hour yielded in that time the equivalent of 1.2-horse power. So while a sperm candle gave 9-candle light per horse power, the gas from an ordinary burner gave 13 candles per horse power. With regard to electricity, it was known that 150 candles per horse power could be realized with the incandescent, and ten times that quantity with the arc light. The object in each case was to obtain as much of the available energy as possible in the form of light. Attention was then directed to a chart illustrating the energy of vision, prepared by Professor Langley, which showed that a very small proportion

indeed was required for that purpose, and that light produced at a point between the yellow and the green in the spectrum produced more than one million times the effect upon the eye than if put in the red or the violet. The lecturer concluded by stating that the problem to be considered by producers of artificial light was firstly to determine what species of radiant energy was most desirable; and then to find out how to produce that particular species to the exclusion of all others. The next thing would be to determine how to measure accurately this energy when put into the form of radiation.

Mr. King called the Professor's attention to the subject of candle power *versus* illumination, which had frequently been discussed at previous meetings of the Association, and which had been exemplified at the meeting by the fact that a Welsbach burner which gave very inferior photometrical results had been selected by several persons as giving the best light. Professor Mendenhall said he thought the resolution of this problem lay along the lines he had indicated—viz., the determination of just what spectrum compounds or wave lengths are desirable in a light. He might mention that Professor Langley used a sheet of printed paper having rather small characters, covered with a piece of white paper having a hole one inch square in it, as a photometer.

The meeting concluded with the usual routine business and votes of thanks, in the course of which Mr. G. Shepard Page was authorized to present the hearty wishes of the Association for the success of The Gas Institute meeting in London. As most of our readers know, this gentleman has already worthily discharged his mission.

ARTESIAN WELL-BORING AT ALDERSHOT.—The Aldershot Water Company have just had two more 6-inch artesian tube-wells added to the system of couple tube-wells by Messrs. Le Grand and Sutcliffe, of London. These wells have been put down to meet the additional requirements of the Government for the Camp; and though the work has been done by hand labour, they were each completed to the depth of 280 feet within the space of five weeks.

PRESENTATION TO MR. L. CLAYTON, OF HUNSLET.—On Thursday, the 12th inst., the *employés* in the firm of Messrs. Clayton, Son, and Co., Limited, of Hunslet, near Leeds, testified their high regard for the Managing Director of the firm, Mr. Lawrence Clayton, by asking his acceptance, on behalf of himself and Mrs. Clayton, of a silver tea-urn, suitably inscribed, on the occasion of the twenty-fifth anniversary of their wedding. The testimonial was subscribed for by whole of the workpeople—nearly 200 in number—and was offered as an evidence of their appreciation of the services rendered by Mr. Clayton in having, for a period extending over a quarter of a century, developed and built up an industry—the manufacture of gasholders, gas plant, &c.—which has benefited the township of Hunslet to a very material extent. The presentation was made by Mr. C. Barrett, who said it was the spontaneous offering of the *employés*, and it afforded evidence of the kindly feelings entertained by the donors towards the recipients. He believed that this feeling was reciprocated on their part; and he trusted that the harmonious relations hitherto existing between employer and employed at the works would not only continue but increase. He heartily wished that Mr. and Mrs. Clayton might long enjoy the gift bestowed upon them in commemoration of their silver wedding, and that the future career of the firm would be signalized by increased trade and prosperity. Mr. L. Clayton, on behalf of himself and Mrs. Clayton, acknowledged the gift in appropriate and felicitous terms.

PRESENTATION TO MR. L. T. WRIGHT.—On Monday last week, the seven principal officials of the Nottingham Corporation Gas Department waited upon Mr. L. T. Wright, Assoc. M. Inst. C.E., F.C.S., at his office, for the purpose of asking his acceptance of a diamond ring, as a small memento of the pleasant relations which had subsisted between them since his occupancy of the position of General Manager of the department—a position he is about to relinquish in order to undertake the duties of Engineer and General Manager of the Buenos Ayres (New) Gas Company, as already announced in our columns. The presentation was made by Mr. S. Tagg, Superintendent of the Radford station, who expressed his regret (in which all his colleagues joined) at the approaching severance of their connection. Mr. Wright had, he said, by his straightforward and gentlemanly bearing, won the hearts of all with whom he had come in contact; and this would often be borne in mind when he was thousands of miles away. He pointed out that the ring could not by any means be taken as adequately representing the good wishes of the staff Mr. Wright would leave behind him. Whilst all deeply regretted the loss, they could not help congratulating Mr. Wright on his appointment to such an influential position as that which he had just accepted; and said he was sure all those, not only in the room, but in the various departments of the undertaking, would join in wishing Mr. and Mrs. Wright and their family a pleasant voyage, a prosperous sojourn in Buenos Ayres, and a safe return to England. Mr. Wright, in responding, stated how regretfully, for many reasons, he was leaving them; for a better staff of chief officials no man need wish to have. He remarked that the gas undertaking, being now one of great magnitude, with extensive ramifications, needed watching with a very keen eye by the various heads of departments; no one better than the principal knowing the great care that was necessarily daily required. He again heartily thanked them for their kind words and good wishes.

Register of Patents.

GAS PRODUCERS.—Bull and Co., H. C., of Poultry, E.C. No. 10,205; July 21, 1887. [8d.]

This invention relates to the generation of water gas, made by passing superheated steam through a body of coal or coke previously raised to a state of incandescence.

The apparatus is of the double chambered type—one of which chambers constitutes the steam superheater, and the other one the chamber in which coal is firstly distilled of its volatile constituents, and then the coke thus made in it is converted into gases. The process of gas making is an alternating one; that is, the coke in the fuel vessel is first raised to a state of incandescence by forcing air through it, and the gases resulting therefrom are burned in the superheating chamber, by which it is also raised to incandescence. The flow is then cut off; and steam is passed in an opposite direction, first through the superheater and then through the fuel vessel. In the first operation—the blowing and heating up—coke is preferably used as the fuel; and the air used is preferably previously heated. In passing through the coke, oxygen of the air uniting with the carbon of the fuel becomes converted into carbonic acid first, and subsequently into carbonic oxide of a high temperature. This, together with the nitrogen, passes up and around the retort, and over into the superheater, where it is supplied with air. Combustion of a high temperature takes place here, and the products of combustion are passed over the brickwork surfaces, by which a great portion of the heat of the gases is taken up and stored. The gases are then led from the superheater into a chimney or other place of disposal. After the apparatus has been subjected to this operation for a certain time, the air is cut off, and steam is passed through the apparatus in the reverse direction—first passing up and over the heated brickwork, whereby it becomes very much superheated, and then through the fuel in the gas-making vessel. The retort of the gas-making vessel, previously to the turning on of the steam, is filled with briquettes of coal, and the highly heated steam surrounding the retort, before it enters the fuel at a lower level, causes the distillation of the illuminating and other volatile gases of the coal, and converts it into coke. In passing through the incandescent coke, the steam is converted ultimately into carbonic oxide and hydrogen; and the gases thus made are led into a suitable main.

The illuminating gas may, after being freed from tar and ammonia, be re-admitted to the apparatus with the steam, and sent through the incandescent fuel and delivered into the gas-main.

Between the processes of reviving and gas making, steam is admitted to drive out any air or gas that may have accumulated on the producer side of the gas and air valves of the gas-making chamber, thereby rendering the apparatus free from explosions.

The particular form of apparatus preferred for carrying out this invention is constructed substantially as follows. The gas producer consists, as already stated, of two chambers preferably round, lined with fire brick or other refractory substance, connected together by a pipe near their upper parts, which is also lined. One of the cylinders has, on the inside, a conical retort, made of fire-brick or other suitable material, occupying a certain amount of its length from the top, and being (say) about half the diameter of the inner lining wall of the cylinder. The other has inside a central cylinder of brickwork, communicating with an air-valve at its bottom; and is surrounded by diverging or radiating walls forming large heating and regenerating surfaces. The first or gas-producing cylinder is provided with three valves—one for the admission of hot air for the purpose of reviving the fire, another for the outflow of gas to the gas-main, and the third (a steam-valve) which is used to clear the pipes first of gas and afterwards of air. The second or regenerating chamber is also provided with three valves—one for the admission of air through the central brick cylinder into the combustion chamber at the top, another communicating with a culvert leading to a chimney, and the third (a steam-valve) connected with a steam-main leading from the steam generators. The top of the conical retort in the gas-making chamber is fitted with a lid which can be readily opened or closed, and provided with a pipe to convey the volatile gases to an ordinary hydraulic main. For a continuous production of gas, two or more producers are used in battery; some being revived by the admission of hot air, while one is producing gas by the admission of steam.

REGENERATIVE GAS-LAMPS.—Körber, J. W., and Streuth, J. W., of Düsseldorf, Germany. No. 7386; May 18, 1888. [8d.]

This invention relates chiefly to the supply of air to the bottom of a gas-lamp, by an arrangement of tubes; to the peculiar construction of the regenerator; and to the arrangement for enabling the ignition of the lamp to be effected from the outside of the glass shade.

Fig. 1 is a longitudinal section of the whole lamp; and figs. 2 and 3 are a vertical section of the burner (with the bottom prolongation for air

supply) and a horizontal section of it. Figs. 4 and 5 are a vertical and a horizontal section of the regenerator.

The lamp consists of certain parts not novel. Gas is supplied through the tube *a* to an angular Argand burner *o*, which is in communication with the bottom part formed by tubes *D* arranged in the form of a ring for the supply of air from underneath. They are in communication at the bottom with the casing *L*, and at top with an air chamber *N*; the latter having inside a projecting edge, and also a strainer placed within it for the purpose of distributing and balancing the supply of air flowing out against the lower surface of the flame. The casing is provided laterally with a number of perforations *l*, serving to conduct air to the inner surface of the glass shade. Over the casing a deflecting disc *m* is slid on to the tubes *D*, and serves to deflect the air flowing in through the perforations from its course to the burner, and to direct it past the inner surface of the glass shade whereby this latter is kept cool, and any unsteadiness of the flame prevented. The greater portion of the air necessary for the thorough combustion of the gas, and for producing an intense white flame, is supplied through the regenerator *C* to the upper surface of the flame. This regenerator has both inside and outside the form of an inverted truncated cone, with double wall or periphery forming an annular air passage *R* and collecting chamber for the escaping products of combustion. Across the air-passage are fixed a number of nozzles *r*, zigzag underneath each other, through which the products of combustion must pass in their course towards the discharge-tube, and so heat the surface of the nozzles as well as that of the truncated cone to a red heat. The conical form of the regenerator and the direction of the nozzles is said to cause the products of combustion to impinge against its surface in a more or less normal direction, thus communicating to it a greater heat than in the case of cylindrical regenerators. The requisite air supply takes its course to the flame in the direction of the arrows *w*; but it cannot arrive there in a direct line, as it must impinge against and around the surface of the zigzag nozzles in a winding direction, and over a relatively large heating surface, thus attaining a far higher temperature than if it had a direct course.

AUTOMATICALLY LIGHTING STREET LAMPS.—Kincaird, S. B., of Guildford. No. 5126; April 6, 1888. [6d.]

This invention relates to the construction of a self-lighting gas-burner by causing a small increase of pressure of the gas supply, by acting on a moveable diaphragm, to augment disproportionately the supply to the burner, and at the same time to operate an auxiliary igniting burner, thus enabling any one or more gas-lamps on a main or service to be lighted up and extinguished simultaneously from a distance.

In the engraving the gas-burner *A* gets its supply of gas from the pipe *Z*, through the valve *S*; the cock *D* regulating the supply, while always, by the extent of the grooves in the plug, leaving the way open from the pipe *Y* to the igniting burner *C*. *B* is a screen, with ventilating holes (as shown) at the bottom, to protect the igniting flame from draughts. *L* is the body of the apparatus, attached by *V* to the gas-pipe in place of an ordinary burner. The plate *G* is hinged to this body, and connected by the diaphragm *K* (of oiled leather or other suitable material) secured by the screwed-down rings *M* and *N* to *L*. *F* is a weight or adjustable spring, according with the pressures for which the contrivance is required to act. *S* is the main valve, which on an increase of pressure of the gas in *L* raises *G*, and the block *W* is thus forced open by the spiral spring shown by the dots—thus supplying gas to *A*. The screw *H* is so adjusted that the piston *P* rises at the same time by the action of its spiral spring; thus first letting gas by its lower valve *T* to *C*, hitherto supplied only through the bye-pass regulated by the screw *R*, and next, when this has kindled *A*, closing the opening *Q*, and extinguishing the flash-burner. On a reduction of the pressure, the weight *F* causes *G* to fall; *Q* is opened, and *C* lights up; then *S* and *P* are both forced home; *A* is extinguished; and *C* (now fed only through its bye-pass) burns at its minimum. *E* is a cover with perforations to admit air.

APPLICATIONS FOR LETTERS PATENT.

10,186.—CAMPBELL, A., and BOYD, W., "Improvements in purifying or treating coal gas and other gaseous or liquid products of destructive distillation, and in part applicable in the alkali manufacture." July 13.

MR. HUNT'S CRITICISMS ON MR. CARPENTER'S PAPER.

SIR,—I do not propose to encourage the "circular-of-inquiry" style of "Your Occasional Correspondent, A. B.," whoever he may be, but should just like to point out to him how little he, or the cause he champions, benefits by his fuel comparison.

Of the yield of coke at Birmingham, 23 per cent. is used as fuel, equalling 9·6 bushels per ton of coal carbonized; while the South Metropolitan Company uses 20 per cent. of the yield, or nearly 10 bushels per ton of coal carbonized, being about 4·10ths of a bushel more than at Birmingham. Moreover, "A. B." has omitted all mention of the tar used for fuel by the South Metropolitan Company, over and above this consumption of coke; and it is strange if this omission be accidental, since the fact is expressly noted in "Field." According to the half-yearly reports of the Company, the total quantity of tar thus consumed during the year 1887 amounted to 2,282,961 gallons, equal (see Mr. G. Livesey's letter to the JOURNAL for Sept. 19, 1886) to 32,614 chaldrons of coke. Multiplying these by 36, and dividing by the total coal carbonized we get an additional fuel consumption equivalent to 2·1 bushels of coke per ton of coal carbonized. The comparison thus becomes about 2½ bushels per ton in favour of Birmingham.

Or, taking the value of this fuel-tar as stated in the South Metropolitan Company's report dated Aug. 5, 1887, at 1½d. per gallon, its total value is £11,890 8s. 5½d., or 5½d., per ton of coal carbonized, the whole, and more than the whole, of which, appears to be saved in Birmingham.

According to "A. B.," I am entitled to appeal to this as testimony in favour of my proposition; and it may appear to be the more remarkable because I am free to admit, in response to his questioning, that it was the South Metropolitan Company which first essayed to set the fashion of regenerative firing in this country. But he is quite wrong in supposing that I saw in London the first workable regenerative furnace used in England; the fact being that I have never seen any such in London. Some attempts have, I believe, been made in this direction; but nothing seems to have come of them—absolutely nothing, I might have said, but for fear of again wounding the susceptibilities of "A. B."

Birmingham, July 21, 1888.

CHAS. HUNT.

THE PHOTOMETER QUESTION AT THE GAS INSTITUTE MEETING.

SIR,—In your issue of the 17th inst., Mr. W. Sugg, in his own kindly way, criticizes my paper on "Photometers," read at the recent Gas Institute meeting. He remarks that the "portable" photometer has never received the sanction of the Standards Department of the Board of Trade, and appears to argue therefrom that its indications are unreliable. As a matter of fact, not one of the photometers at the 17 Metropolitan gas-testing stations has received such sanction, as it is not required. The only authority concerned is that of the Gas Referees, who had the "portable" photometer in their possession some time back, and returned it, with an intimation that they were perfectly satisfied that it was a good and correct instrument.

Mr. Sugg then proceeds to criticize the tables, and says that on the third day (Table No. 3, photometer No. 1) the "pairs of readings agree again, practically; the difference being that the Evans photometer read 0·1 candle lower than the open bar." If Mr. Sugg had said that the first pair of tests so agreed, he would have been correct; but he infers that they all agreed. The following are the figures; and I do not think that a difference of two candles (see third pair) can be called an agreement:—

Evans.		Open Bar.	
17·2	Greatest difference, 2 candles.	17·3	Greatest difference, 1·3 candles.
16·8		16·0	
18·0		16·0	
17·6		16·6	
16·0		16·5	

Average 17·1

Average 16·5

The fourth day shows an average agreement in the first pair of tests, as is not uncommon with the Evans photometer—the first test generally being fairly satisfactory; but in the second pair of tests, the difference is 1·3 candles. The readings on the fifth day give an average of 16·6 for the Evans, and 15·7 for the open bar, or a difference of 0·9 candle. On the sixth day we have 17·5 for the Evans, and 17·2 for the open bar—not a great difference truly! But how obtained? I submit, by sheer accident. These are the figures:—

Evans.		Open Bar.	
17·3	Greatest difference, 1·9 candles.	17·3	Greatest difference, 0·2 candle.
18·5		17·1	
16·6		17·1	

And yet Mr. Sugg calmly says: "And so on every day I find pairs of readings, sometimes agreeing completely, and sometimes with very slight divergencies one way or the other, until the ninth day, when we have the 'corruption of good manners' by an 'old converted' Evans," as Mr. Sugg neatly puts it. Now, while I candidly admit that the "old converted" photometer is a bad example of a bad class, I shall be pleased to introduce Mr. Sugg to one of the very latest pattern Evans, which persistently returns 16·5 candles as the value of a 2½-inch flame—a result impossible of attainment by fair means on an open-bar photometer. Mr. Sugg asks why results as concordant as the above should not always be obtained. I reply that they are always obtained; and that they are so contradictory and confusing that I have frequently had an examiner, who has been accustomed to accurate work in other branches of science, look at the instrument in wonder, and seriously ask, "What is the good of using it?"

My contention that the Evans photometer is a mistake is upheld by such experienced authorities as Mr. Heiseh and the late Dr. Letheby; and I can see no reason whatever for its retention. It must be distinctly understood, however, that in this I do not attach any sort of blame to the makers. They have had a difficult task to make a faulty thing workable at all; and the excellent work turned out by them is a guarantee of their care and skill. Formerly all the faults of the Evans

photometer were ascribed to the candles. But it is now demonstrated that it is the instrument that is the greater sinner of the two; and I submit that it should be removed from all testing-rooms at once.

I may say, in reference to Mr. Sugg's remark anent the Gas Referees, that I have no desire to interfere with their discretion or their duties; but, as I have found certain facts, I deem it my duty to put them forward for the information of all concerned. A dispassionate consideration of these facts, and the daily experience obtainable, will result in the establishment of the arguments contained in my paper. Instead of the few figures given, I could have multiplied them a hundredfold. As it is, they are merely illustrative of a state of things existing in daily work, which should not be allowed to continue now that the true cause is known.

I confess that I am not now prepared to resume a discussion on the bending of the wicks of candles, &c., as re-started by Mr. Young. Candles have been heartily abused by being used in unsuitable instruments, and as often, it is true, in unsuitable rooms; but I cannot see any advantage in rediscussing a threadbare subject. Our efforts will be more profitably devoted to the speedy introduction of one of the new and reliable standards, and thus to the attainment of more serious and accurate work. The comedy of "The Candles in an Evans Photometer" has been played long enough, and should be brought to a close as speedily as possible.

Spring Gardens, S.W., July 18, 1888.

W. J. DIEBEN.

SIR,—As Mr. Young, in his letter to the JOURNAL for the 17th inst., refers to tests made by me at this office, I think it right to inform you that his conclusion, that those tests (which are taken daily, not occasionally, as might be inferred) confirmed the testings on the Evans photometer in Jewin Street, is not correct as regards the observations in the foggy weather to which he refers; but, not being official, they cannot be published.

July 23, 1888.

CHAS. HEISCH,
F.C.S., F.I.C., &c.

THE INCREASED DEMAND FOR COKE.

SIR,—I do not know whether or not your invitation to your readers to give an explanation of the increased demand for coke in England is to be considered to have been extended to your foreign subscribers; especially to those who, like myself, write English imperfectly. But, at any rate, I venture to submit an explanation, rather for the sake of what I can learn than for the information I am able to give to others. Perhaps one fact connected with my country of residence (Spain) may facilitate my hitting on the true explanation. It has always been a puzzle to my mind to understand the low price that gas coke fetches in England, as compared with what I understand is its intrinsic value, rationally estimated, in relation to other fuels. Merely considered in its absolute value as a heat-producing material, without thinking of any special application, I consider that gas coke is equivalent in value to large steam coals, with an addition to such price of 12 per cent. But, besides this, gas coke has merits of its own for certain purposes, which enhance its value (say) to about 25 per cent. on the price ruling for large steam coal. Gas coke is such a fuel as can be used in heating-stoves of the Chuvinsky type, and the like, without producing smoke and avoiding the great waste of heat experienced with open fires. Next to this, cooking-ranges heated by coke are very convenient and economical; even when paying for coke double the price usually paid for coals used for cooking in ordinary appliances in England. Not to cite a great number of cases, let me say that, gas coke being the material preferable, after anthracite, for producing Dowson gas and water gas, its value must be considered far superior to an equal weight of such coal as would do similar service to that obtaining from coke applied to such purposes.

Is it prejudice and habit that have been the cause in England of gas coke, instead of fetching a price equal to 25 or 30 per cent. above the average of large coal, being sold at a considerable discount on this price, and even then not easily and generally? Although I am acquainted with English habits and customs, I could not give a positive answer to this question; but I am inclined to believe that there is no sound reason why such coke in England should be so depreciated from its intrinsic value. My impression is that in my own country, as also in France, the value of gas coke is exaggerated. It is generally 50 per cent. more than the cost of gas coal on the spot. So that where this kind of coal costs 14s. a ton, it is almost certain that coke will find a market at 21s., or even more. Of course, this may depend on the small quantity of coal carbonized in each gas-works; but this is no doubt compensated by its restricted employment for industrial purposes, as well as by the limited use of machinery and apparatus in which coke could be consumed in Spain. But as to England, where there is no limit to the quantity of coke that ought to be saleable for use in existing machinery and apparatus—if for no other purpose, to be converted into producer and water gas—I could understand coke being sold at its intrinsic value as fuel, after any transformation that may be required; but in no case can I see why it is sold below that value. This is so clear to my mind that I really believe it must be so to every one else's; and most likely a movement is going on in England to use gas coke for domestic heating and cooking, and for producing industrial gases, though such movement has not yet been sufficient to bring the price to its proper level, as will be the case when the change has become general. But, in the meantime, it may have already advanced sufficiently to add quietly to its former applications such others as may be causing that increased demand which will, in the course of time, cause the present underrated value of coke to disappear, and perhaps even make it (as is the case in Spain) worth 50 per cent. more than large coal, ton for ton, not on account of its intrinsic value, but of its additional convenience.

I have often thought that, after the practical demonstrations made by Messrs. Crossley Bros., Limited, and the Dowson Gas-Producer Company of the quantity of gas coke they consume to obtain 1-horse power, the electric light in England ought to be produced in the cheapest way, in most cases, with Dowson gas used in "Otto" gas-engines, until there is a change in the prices. In Spain, on the contrary, I know of a case in which the equivalent heat of 30,000 tons of coal could be obtained without any cost, by selling gas coke (at the current price of the market) at more than double the cost of the coals.

In conclusion, I may say that, in my opinion, the present demand for gas coke in England depends on the fact that it is sold at less than its intrinsic value. I have before me the "Analysis of the Accounts of Gas Companies and Corporations for 1886;" and I notice that most of them only realize 30 per cent. of the cost of their coal by the sale of their coke. But I think it will not be until they make 60 per cent. by it that they will be selling it at its real value.

Madrid, July 11, 1888.

A SPANISH GAS MANAGER.

MECHANICAL v. HAND STOKING AT THE MANCHESTER CORPORATION GAS-WORKS.—In the final paragraph (on p. 126) of Mr. West's letter on the above subject in the JOURNAL last week, the saving effected at the Rochdale Road works, where Mr. West's machinery is in operation, was, by a typographical error, printed as 1-646d., instead of 8-646d. per ton.

THE ISSUE OF STAMPED SHARE CERTIFICATES.—A Country Secretary writes: "I shall feel obliged if you will kindly inform me whether statutory gas companies are required to issue their share certificates under a penny embossed stamp; and likewise if this provision of the Stamp Acts is obligatory on all limited liability companies."

HOUSE OF LORDS.

MONDAY, JULY 16.

The Nelson Local Board Bill was read the third time, with the amendments; further amendments made; Bill passed, and sent to the Commons. The Electric Lighting Order Confirmation Bill (South Metropolitan Order) was read a second time.

TUESDAY, JULY 17.

The Lancaster Corporation Bill was reported, with amendments.

FRIDAY, JULY 20.

The Hexham Local Board Bill was read the third time, with the amendments; further amendments made; Bill passed, and sent to the Commons. The Bristol Water Bill and the Lancaster Corporation Bill were read the third time, with the amendments, passed, and sent to the Commons.

HOUSE OF COMMONS.

MONDAY, JULY 16.

BRIBERY OF OFFICIALS OF PUBLIC BODIES.

A Bill for the more effectual prevention and punishment of bribery and corruption of and by members, officers, or servants of corporations, councils, boards, commissions, or other public bodies, was ordered to be brought in by Lord Randolph Churchill, Sir R. N. Fowler, Mr. Jennings, Mr. Whitbread, Sir H. James, and Mr. R. Power. This was subsequently done, and the Bill read the first time.

WEDNESDAY, JULY 18.

The London Sea Water Supply Bill (Lords) was read the third time and passed.

THURSDAY, JULY 19.

THE LOCAL GOVERNMENT (ENGLAND AND WALES) BILL AND THE LONDON GAS AND WATER UNDERTAKINGS.

In the course of the consideration, in Committee, of the Local Government (England and Wales) Bill,

Mr. FIRTH moved the following clause:—"A County Council shall have the same powers of promoting and opposing Bills in Parliament, and otherwise acting for the promotion and protection of the interests of the inhabitants of the county, as if the County Council were a governing body within the meaning of the Act of the session of the 35th and 36th years of the reign of Her present Majesty, cap. 91, intituled, 'An Act to authorize the application of funds of municipal corporations and other governing bodies in certain cases,' and as if the county were the district in which such governing body had jurisdiction: Provided that so much of section 4 of the said Act as requires any consent of owners and ratepayers shall not apply to any expense incurred by a County Council; and provided further that nothing in section 2 of the said Act shall prevent the London County Council from promoting any Bill for the purchase or regulation of the undertakings at present supplying water and gas to any part of London, or any of them, or for the provision of a new supply of water, gas, or light to London or any part thereof." He said he thought it was most desirable that this power should be given; and he hoped the Government would accept the clause.

Mr. RITCHIE said the powers possessed by the Metropolitan Board and the Courts of Quarter Sessions in this respect were handed over to the County Councils; but, not satisfied with this, the honourable member had proposed to apply the Borough Funds Act. He thought the Committee ought to be very careful as to removing restrictions without putting anything in their place. There was another argument he would venture to press on the Committee. The whole question of Private Bill Legislation had been undergoing examination. None of them, he thought, were satisfied with the present condition of things; and, under the circumstances, he should ask the Committee not to accept the clause.

Sir W. HARCOURT said that when the Select Committee of 1880 considered the subject of the water supply of London, they specially pointed to the necessity and the advantage of some body representing the Metropolis having the power to supply water; and, there being no general body representing London which could undertake this duty, they recommended the constitution of a special body for the purpose. Under the Bill now before the House, they were creating a general representative body for London; and they ought not to launch this body under a prohibition which would perpetuate a monopoly in the hands of the Water Companies. It therefore appeared to him that the concluding part of the amendment was deserving of the consideration of the Committee.

Mr. LAWSON regretted the refusal of the President of the Local Government Board to accept the amendment. The people of London were, he said, placed at a great disadvantage by not having the municipal powers that were possessed by the other great towns of the country. If the right honourable gentleman would hold out any hope of the clause being accepted, might it not be possible to strike out the part of it which referred to the new supply of water or gas for London, because there were arguments against it which were not applicable to the other part? The ratepayers of London felt strongly the necessity of possessing the municipal powers included in the clause.

Mr. ISAACS believed that if the honourable member for Dundee (Mr. Firth) would consent to some modification of the clause, he would find himself supported by Metropolitan members on both sides of the House. It was felt that there would be danger in a municipal body being entrusted

with powers which would give them the opportunity of setting up rival schemes for supplying water and gas; and therefore he would suggest that the honourable member should make the concluding paragraph read to the effect that nothing in section 2 of the Borough Funds Act should prevent the London County Council from promoting any Bill for the purchase of undertakings which were at present supplying water or gas to London or any part thereof.

Mr. WOODALL trusted the President of the Local Government Board would respond to the appeals so generally made to give to the county authorities the powers proposed in the clause, limited by the provision that they should not have power to set up competing works.

Mr. RITCHIE asked the honourable member for Dundee whether he would be satisfied if the Government, recognizing the force of the arguments addressed to them, consented to some amendment being introduced at another time and place, giving to the County Council for London power to promote Bills for the purchase of the water undertakings.

Mr. FIRTH regretted that he was unable to answer in the affirmative, because the very strong Committee which sat in 1880 were unanimously of opinion that there ought to be given to any central authority power to initiate a new supply or to purchase or regulate existing undertakings. He could not consent to any settlement which would abate one jot of the powers which that Committee declared a London central authority ought to possess—viz., initiation, regulation, or purchase.

Sir W. HARCOURT remarked that the Committee in 1880 pointed out that the power to purchase was utterly worthless without the power of competition. He was informed that a new supply could be established at less than half the sum asked for the London water-works in 1880. Of course the power to purchase at a reasonable rate entirely depended upon the purchasers being able in the alternative to furnish a supply themselves. This was the key to the whole matter. He could not understand why the great public bodies to be created by the Bill should be refused the power to compete with existing companies.

Mr. RITCHIE said the right honourable gentleman did not seem to be aware that this was a power which was not possessed by any municipal corporation in the kingdom.

Sir W. HARCOURT observed that he was perfectly aware of it. He was speaking of London only; and he said that the Committee of 1880, in a unanimous report, recommended that London should have this power. They pointed out that the right to compete was the basis of the whole thing; and if they refused it a reasonable purchase could not be made.

Mr. CHILDERS said that, having very carefully watched Private Bill Legislation for some time, he had come to the conclusion that, although with respect to the small boroughs and district councils it might not be prudent to grant the unrestricted power proposed, it was the essence of such local government as they were trying to establish, that the County Councils and great boroughs should have the power both of promoting and of opposing Bills. The absence of such power, or the restraint put upon local authorities in this matter, had hampered these bodies. They ought to have confidence in the authorities they were about to create, and pass this clause.

Mr. RITCHIE thought the fact of the right honourable gentleman (Mr. Childers) only having arrived at a conclusion after very long and anxious consideration was an argument why the Government should not ask the Committee and the House to come to any settled determination to insert in the General Bill before them a proposal such as had now been made. The Government had never pretended, in setting up these new authorities, that they were arming them with all the powers which at some other time they might give them, or even with those which they now thought the Councils ought to possess. They had felt that if they were to embark on so large a field of discussion it would be doubtful, to say the least, whether they would be able to pass the Bill in the course of one session. At present all gas or water companies were specially protected against any public body presenting a Bill to Parliament for the purpose of setting up a competing supply. If the Government had proposed to do away with this restriction, he thought that such opposition would have arisen that it would have been perhaps impossible to get the Bill through at all. The course the Government had adopted was one which would have commended itself to right honourable gentlemen opposite if they had had to carry through Parliament in one session so great and comprehensive a measure as the one before them.

After some further conversation, the Committee divided; the numbers being: For the clause, 107; against it, 115—majority, 8.

Mr. FIRTH subsequently moved to insert new clauses giving power to the London County Council, as soon as possible, to submit to Parliament a Bill for the re-arrangement of municipal government and administration within the area of the county of London; and also one "for the purchase or regulation of the undertakings at present supplying respectively water and gas to any part of London, or any of them, or for the provision of a new supply of water, gas, or light to London or any part thereof." He said the question raised by his amendment was this: Should the new London Council be authorized to deal by way of a Bill (to be afterwards submitted, of course, to Parliament) with the important and difficult question of internal administration? It was admitted on all hands that the interior administration of London required re-arrangement; and he submitted that the clause he proposed afforded a solution of a most difficult question which must arise hereafter.

Mr. RITCHIE said it would not be in accordance with his view of the duty of the Executive Government to shift on to the shoulders of the new County Council the duty which the honourable member sought to impose on them. He did not say that in dealing with this matter they might not place a great deal in the hands of the London County Council; but it would not be prudent to overload it with matters of this kind before they had had time to attend to their simpler duties. He quite recognized the importance of the question; and, while he should be glad if it could be left to the London County Council, he did not feel that this would be the proper course to take.

Mr. FIRTH then withdrew the clause referring to the Municipal Government of London, and moved the one dealing with the purchase or regulation of the gas and water undertakings of the Metropolis. Combined with it was a provision for the regulation and inspection of hackney carriages.

After some conversation, a division was taken on the portion of the clause relating to gas and water supply, when the numbers were: For, 106; against, 146—majority, 40. It was therefore lost.

BRIBERY (PUBLIC BODIES) PREVENTION BILL.

On the order for the second reading of this Bill, an objection was raised by the honourable member for Camberne (Mr. Conybeare); whereupon Lord Randolph Churchill, who had charge of the Bill, withdrew it.

The East Stroud and District Electric Light and Power Company, Limited, has recently been registered with a capital of £5000, in £5 shares; and the City of Westminster Electrical Syndicate, Limited, with a capital of £10,000, in £1 shares.

Legal Intelligence.

DURHAM SUMMER ASSIZES.—MONDAY, JULY 16.
(Before Mr. Justice CAVE.)

THE CHARGE OF LIBELLING MR. WARNER.

To-day Richard Cunliffe was charged with unlawfully and maliciously publishing, at South Shields, on April 14 last, a certain defamatory libel concerning William John Warner, Manager of the South Shields Gas Company. The case was heard by the Magistrates at the South Shields Police Court on April 25, as reported in the Journal for May 1 (p. 783); the result being that the accused was committed for trial.

Mr. T. MILVAIN, Q.C., M.P., and Mr. JOEL appeared for the prosecution; Mr. WALTON for the defence.

Mr. MILVAIN, in opening the case, said the prisoner was charged with publishing a libel on Mr. W. J. Warner, who for many years had been the Manager of the South Shields Gas Company. In 1886 there was certain work to be done on behalf of the Company; and advertisements were issued. The work consisted of the construction of a gasholder tank; and the defendant was appointed to the inspectorship of the work, at wages of 50s. a week. He continued in the employment of the Company till the work was completed, and for some short time longer. In February of the present year the engagement terminated. He then made a claim for overtime, which was looked into, and not entertained. The defendant, apparently by reason of this, felt some resentment against Mr. Warner, whom he blamed for his time allowance not being granted. He had also been endeavouring to obtain further employment from the Company; but this was not forthcoming. On the 16th of April he wrote to one of the Directors (Mr. Hall) a letter which contained the charges complained of. [The learned Counsel read the letter, the full text of which was given in the number of the JOURNAL above referred to. In it he stated that the Directors were unaware of the "deceitful and unscrupulous way" in which the Company's affairs were managed by Mr. Warner, through whose "blundering" the tank had cost "over £2000 more than it ought," and was not then finished. He added: "The proofs of what I say are in my possession; and I have determined to issue them to the shareholders, so as to let them know how their Manager fulfils the trust reposed in him. These are only a part of the charges which can be brought against him and substantiated without much trouble." Such a letter, continued the learned Counsel, was calculated to injure Mr. Warner very seriously, casting imputations, as it did, on his honesty; and he at once took steps to institute criminal proceedings against the defendant. The prosecutor had no desire to seek pecuniary damages from the prisoner or to obtain costs from him; nor had he any vindictive feeling against him or desire to imprison him. All he wished was to vindicate his own character; and if the prisoner was prepared to withdraw the allegations, and apologize, the prosecutor had no wish that he should suffer any penalty whatever.]

Mr. WALTON (after consulting for some time with the accused) said: I have spoken to my client, and, after my learned friend's statement; I have suggested to him that he ought in this case to withdraw the plea which he has placed upon the indictment, and make his statement of the circumstances under which the letter was written, which, I think, will satisfy my friend after the way in which he has opened the case. The letter to which reference is made is addressed to Mr. Hall, and was written to Mr. Hall under circumstances which Mr. Cunliffe regarded as of a confidential character. Mr. Hall was a great friend of his own; and Mr. Cunliffe, leaving the situation with a grievance, was induced to communicate to Mr. Hall what that grievance was, as well as certain matters which had been discussed between them. He now feels that he used language which was exaggerated, and which in calmer moments the facts would not entitle him to use. The matters to which he made reference have been examined; and now, taking a thorough view of them, they did not justify the statement. I am instructed to say that it was never Mr. Cunliffe's intention to charge dishonesty, especially as to what he says as to certain wages having been charged to capital instead of revenue account. He admits now that there was no adequate ground for making the charge, and begs to withdraw it; and as his statement was not justified, it is his duty to Mr. Warner to withdraw it. Through me he says it was from a sense of grievance he was led to use the language he employed in the letter. Under all these circumstances, and after the way in which my learned friend has introduced this case, I hope that your Lordship will accept the expression of regret, and that the prosecution will allow the case to be withdrawn.

Justice CAVE: Very well; that will be done.

The CLERK of ASSIZE (to prisoner): Do you withdraw your plea?

Prisoner assented.

Justice CAVE: You have pleaded guilty to publishing this libel. It is a libel which concerns the prosecutor, and him alone. I do not think the public are concerned in it in any way; and therefore I see no reason why the prosecutor may not settle it in this way. I therefore order you to be discharged.

The prisoner then left the dock.

LANCASHIRE WATER SUPPLIES.—The recent rains have considerably increased the quantity of water in store in the reservoirs of several of the Lancashire Corporations. Liverpool, which was on the very verge of a water famine of the most acute kind, added no less than 300 million gallons to its store in the Rivington reservoirs; and the danger of the suspension of the supply is now averted. The Wigan reservoirs have not benefited to the same or a corresponding extent; but the supply is reported to be equal to about four months' requirements at the present rate of consumption. At Bolton there has been a very substantial increase in the quantity of water in store; but it said that the danger of a curtailment of the supply is not yet entirely passed.

THE GAS RESIDUALS PRODUCTS COMPANY.—In the Court of Session (First Division) last Tuesday, the petition presented by the Gas Residuals Products Company, asking for an order to confirm a resolution come to by them to reduce their capital, was before the Court. The Company are chemical manufacturers and distillers of tar and ammoniacal liquor in Glasgow. When they commenced business, they took over various contracts entered into by their predecessors. By the fall in the price of chemicals, losses arose, and were continued until the contracts expired. The capital of the Company has, in consequence, been diminished; and in June a resolution was adopted reducing the capital from £60,000 in 6000 shares of £10 each, to £42,000 in 6000 shares of £7 each—the reduction to be effected by writing off a sum of £3 per share. The Company wished to have this resolution confirmed. The petition was remitted to Mr. C. B. Logan, who recommended that the minute to be recorded should be as follows:—"The nominal capital of the Company is £42,000, divided into 6000 shares of £7 each. At the time of the registration of this minute, 3579 of the shares have been issued, upon which the sum of £5 10s. per share has been, and shall be deemed to have been paid up. The remaining 2421 shares have not been issued." The petition was granted.

Miscellaneous News.

THE MANUFACTURE OF COAL GAS.

LECTURES AT THE CITY AND GUILDS OF LONDON INSTITUTE.

At the City and Guilds of London Institute, Exhibition Road, South Kensington, last Tuesday, Mr. LEWIS T. WRIGHT, Assoc. M. Inst. C.E., F.C.S., delivered the first of a series of four lectures to students, on "Gas Manufacture," the syllabus of which was given in the JOURNAL for the 10th inst. The lectures are on the same lines as those delivered by Mr. Wright last year; and the following is an abstract of the first.

Mr. Wright commenced by saying that it would be impossible to take those present through the practice of gas manufacture; and the utmost he could do was to introduce them to some of the theory that bore on the subject—to show them behind things, as it were. The manufacture of gas, conducted merely as a mechanical operation, was very simple; but directly they began to look behind the operations, and to study the theory, they found it became an exceedingly complicated business. The basis of operations was, of course, coal; and it curiously happened that in this country all the material employed in gas manufacture was coal, and that, too, coming from the same geological formation. The seams which yielded the various descriptions of coal used in gas manufacture contained, as it were, many different kinds; or, in other words, the same seam might give not only a cannel coal, but a caking coal, and gas coals, and even coal that was only suitable for steam purposes. The coal that a gas manager required was, first of all, a coal that gave him a considerable volume of gas of tolerably good, or very good illuminating power. The range of carbon in caking coal was not very great, but still this range, small as it might be, considerably altered the character of the coal. If they took a great run of gas coal, 1½ per cent. of nitrogen was the usual thing. Ash was very variable. Oxygen was an element that should receive some attention; for those coals which contained a large quantity were not the best for the use of the gas maker. The lecturer then referred in detail to a large table he had prepared, giving the composition of various coals; drawing special attention to South Yorkshire, Derbyshire Silkstone, and Nottinghamshire coals. They would see how greatly the coal altered the further they went north of Sheffield. The candle power, it would be noticed, was progressive; and the coke at the same time increased in quantity. It generally happened that the worst gas coals were those which contained the most sulphur; and as they went south they lost almost in everything—they lost in illuminating power and volume, and increased in impurity. Regarding the composition of the South Yorkshire Silkstone and Derbyshire Silkstone coals, there was a vast difference. Looking at the analysis at certain points, they would at once see that they had to deal with a better coal in the South Yorkshire than in the others. Oxygen, moisture, ash, and sulphur would get high as they went south. South Yorkshire yielded the finest gas coal known; but when they came down to Nottinghamshire, they had a bad gas coal—one which, in fact, was not used for gas making. In the case of Newcastle coal the carbon was high. It was very difficult for him to give the yields of gas per ton on exactly the same basis, as the temperature and the manner in which the coal was distilled affected this very considerably. Taking them as nearly as his judgment would tell him would be similar conditions, in practice they would get 10,500 or 10,300 cubic feet out of a ton of Newcastle coal; and working at a similar temperature, 9800 cubic feet out of Nottinghamshire coal. The distinction between the typical Midland coal (South Yorkshire) and the typical Newcastle coal would be that they would get more gas perhaps out of the South Yorkshire, and that of a slightly higher illuminating power. Against this, however, they obtained from the Newcastle coal a higher yield of coke (which perhaps was indicated by the larger proportion of carbon they found in the coal); but the tar was distinctly lower in quantity. The sulphur from South Yorkshire coal was lower than that from Newcastle coal. In the case of the latter, the crude gas very often contained not less than 45 grains of sulphur; whereas from South Yorkshire they perhaps had not half this, when distilled at the same temperature. Therefore these coals were very much prized, because of their richness as regards gas, and their freedom from sulphur impurities.

Referring to cannel coals, the lecturer said they were often found in the same seams and in contact with caking coals; and they occurred, as it were, accidentally—being found in the hollows of the main seam of coal. So that in mining these seams, they often came across these basins, so to speak, of cannel coal. When they did meet with them, if they were to strike them in the centre they would run thinner and thinner until they came down perhaps to only ½ inch thick, and then would reappear again. The same seam, therefore, that contained the caking coals also contained coals of a totally different character. He might say that, having carefully studied the formation of these coals, as far as observation and analyses would enable him to carry out the investigations, he had come to the conclusion that all the materials forming the different sorts of coal had been deposited by aqueous agency—the materials that formed the coals had been carried by water and placed *in situ*; and if they examined any caking coal the thing that would most strike them would be the laminated character of the coal. The "silk" coal was fibrous vegetable matter—trees, and things of that kind, that had been submitted to the action of fire, and had had their volatile products very largely distilled away from them. It would be obvious to them that the best of timber that had been burned would have a different specific gravity to that of timber that had not been burned; and water in running would, according to its velocity, have the power of sorting out materials of different gravities. From South Yorkshire to Nottinghamshire, they found, as they went South, that the "soot" coal increased rapidly; and as it increased, the coal became less valuable to them as gas makers. In practice they generally called any hard coal, that did not show any prominent signs of lamination, cannel; whereas if they took any piece of caking coal, the signs of lamination were immediately prominent, so that it could be easily split up. The cannel coals, as a matter of fact, were laminar, although they could not see the laminæ. The laminations were not observable unless the coal was burnt away, and the ash examined; and when this was done they could always notice the laminar structure of the cannels. These cannels, which were found in the same seams with other coal, sprang really from the same material as that coal; but the material had been sorted, as it were, by the carrying action of the water. He then called attention to the richest cannel coal he knew of—Australian cannel, from which could be obtained about 16,000 cubic feet of 50-candle gas.

Considering the distillation of coal as a mechanical operation, the lecturer again remarked that it was a very simple matter; but directly they began to regard it as a chemical operation, it became an altogether different thing. The results of the distillation of coal would depend entirely upon the temperature employed. The question that would perhaps be most interesting to them would be at what temperature the bituminous portion of the coal became converted into gas. They might take it roughly that if they were to submit their coal to a temperature of 1000° Fahr., they would get out of it all the volatile matter. However,

in practice this was an exceedingly low temperature, and distillation would proceed very slowly at it, and they would procure a small quantity of illuminating gas and a large amount of tar. Of course, if they maintained the temperature of the retort higher than this, fresh conditions would set in. Supposing they kept it at 1500° Fahr., the coal would, as soon as it reached a temperature of 1000°, lose its volatile matters; and in coming into contact with the sides of the retorts, these volatile matters altered chemically—altered very largely in their character—new bodies being formed. Supposing they had a temperature of 1500° Fahr., so long as volatile matters were largely coming off the coal, they could not raise the temperature of the coal to more than 1000°; so that if they were to charge a retort that was heated to 1500° outside, they would find that for an hour or two the coal would not materially rise beyond 1000° Fahr.

The lecturer then showed how differently coal behaves at various temperatures, by referring to the results of experiments given in the following tables, which he said had not yet been published:—

TABLE I.—Elementary Composition of the Distillation Products from 100 Parts by Weight of Derbyshire Silkstone Gas Coal Distilled at Low Temperature.*

Products.	Carbon.	Hydrogen.	Sulphur.	Nitrogen.	Oxygen.	Ash.	Totals.
Coke . . .	57.38	1.24	1.05	1.06	1.28	2.96	64.97
Tar . . .	6.11	0.46	0.05	0.06	0.60	—	7.28
Liquor . . .	0.08	1.06	0.12	0.22	8.30	—	9.78
Gas . . .	7.56	2.85	Trace	0.36	1.46	—	12.23
Purifiers . .	0.22	0.02	0.39	0.01	0.56	—	1.20
Totals . . .	71.35	5.63	1.61	1.71	12.20	2.96	95.46

Yield per ton: Coke, 12.94 cwt. Tar, 14.38 gallons, of 14.35 sp. gr. Gas, 7582 cubic feet, of 18-candle illuminating power.

* The temperatures, Mr. Wright incidentally remarked, at which these experiments were carried out were lower than they would work at in practice.

TABLE II.—Elementary Composition of the Distillation Products from 100 Parts by Weight of Derbyshire Silkstone Gas Coal Distilled at High Temperature.

Products.	Carbon.	Hydrogen.	Sulphur.	Nitrogen.	Oxygen.	Ash.	Total.
Coke . . .	57.95	0.70	0.77	0.47	1.24	2.97	64.10
Tar . . .	4.78	0.38	0.06	0.05	1.18	—	6.47
Liquor . . .	0.08	1.06	0.13	0.21	8.30	—	9.78
Gas . . .	8.53	3.42	Trace	0.86	2.30	—	15.11
Purifiers . .	0.38	0.04	0.74	0.02	0.93	—	2.11
Totals . . .	71.73	5.61	1.70	1.61	13.95	—	97.57
Coal . . .	75.71	6.27	1.72	1.72	11.59	—	100.00
Error and loss	- 3.98	- 0.66	- 0.02	- 0.11	+ 2.36	- 0.02	- 2.43

Yield per Ton: Coke, 12.82 cwt. Tar, 12.01 gallons. Liquor, 21.6 gallons, of 1.207 sp. gr. Gas, 11,189 feet, of 15.3-candle power. Candles per ton, 34,238.

Alluding to Table II., Mr. Wright said that he had no record of the temperatures, as it was exceedingly difficult to get one of such high heats. In this table, the temperature of the outside walls of the retorts might have been approaching 2000° Fahr.; and in Table I., it might not have been more than 1500°. He directed special attention to the differences exhibited. If they looked at the production of gas, they would see that they obtained more carbon and hydrogen in the gas by increasing the temperature; so that it simply amounted to this—that at a low temperature the products they made were products which would, on the cooling of the gas, condense into oils; and if these products were submitted to a high temperature, they in their turn became destroyed and would produce illuminating gas. In the case of the low-temperature experiments, they obtained gas of 18-candle power; while in the high-temperature experiments they had 15½ candles. The difference of illuminating power was not in practice so great as was shown in these particular experiments. In regard to tar, they had a volume of 14½ gallons of tar of very low specific gravity in Table I., and possibly the tar contained 15 per cent. of free carbon. In Table II., they had 12.01 gallons, which would contain from 25 to perhaps 30 per cent. of its weight of free carbon. He specially wanted his hearers to remember some points by which they could detect whether the coal was being distilled at a low or a high temperature. Nothing could be more suggestive than the character of the tar. When they distilled the coal, if they found that they had a gravity, with the caking coal, as low as in Table I., they would know at once that the coal had been distilled at a low temperature; and if they found a low percentage of free carbon, this would be an indication also that it had been distilled at a low temperature. Reverse remarks would apply to high temperatures. There was a general idea that if the temperature of distillation was increased, the ammonia would be destroyed; but he thought that in the range of practice they need not fear this. They might take it that a high distillation temperature, especially in combination with a thin layer of coal in the retort, was not conducive to the best gas coke. The finest gas coke seemed to be produced at a lower temperature.

The lecturer next dealt with the "turns" in the quality of the gas at various periods of the charge. That was to say, they charged a retort; and at the time they charged it the retort might have an internal as well as an external temperature of 2000° Fahr. Silver, perhaps, would melt in the retort. The coal was put in; but they could not get the coal beyond 1000° Fahr. However, when the retort was first charged, they got off a large volume of gas. But the greatest quantity did not appear to come off precisely at the first charging of the retort, but generally in the second quarter of an hour. After this the quantity of the gas was continually diminishing. At the same time that the yield of gas was naturally diminishing, the quality of that which was coming off was also falling away. What he had to say in this connection was quite novel, and had never been published. If they took these quarter-of-an-hour periods, they would find the quality of the gas approximately as follows:—The first quarter-of-an-hour, 21 candles; the second, 18; the third, 15½; the fourth, 14; then 13, 8½, 7, 6, and so on. He might tell them that in practice the actual illuminating power of the bulk of the gas was higher, and considerably higher, than the results that they would expect to get from these subsidiary analyses. This led him to something else interesting. While the yield of gas was going from a high rate down to nothing at all, the candle power was at the same time going down to nothing, so that there would be times when they would be having gas entering the hydraulic main of high, and at other times of

low luminosity. Now supposing two retorts placed side by side were being charged together in such a manner that they would be worked off at one time; then the gas obtained for these would be varying from 21 down to (say) 7 or 6 candles. Supposing now one retort only was charged, and then the other one when the bad gas had come off the first one. Let them suppose that if he (the lecturer) charged a retort on this system with a ton of coal, he might get 10,500 cubic feet of 16½-candle gas. But supposing when this was half burnt off, he charged another retort so as to let the gas mix with that which was coming off the other, he would get a different result; he would get the same volume of 17-candle gas in the same way that he had previously explained. In other words, if they were to collect the gas coming off in the retorts every quarter of an hour, certain results would be obtained which would lead them to believe they would get a certain result from the whole quantity of gas; but the result was really higher as a matter of fact. This was confirmed by practice and by experiment. If they allowed the gas from partially burnt-off charges to mix with gas coming from coal at a very early stage, they would get a better result than if all the retorts were charged at one time. This was because the low-quality gas was able to carry a much higher complement of hydrocarbons; it was a question of the carrying power of the gas. This matter which he had been speaking upon, would be interesting in the testing of coal. When they tested coal, especially when they tested it in the laboratory, they tested a single charge. They would say that the coal yielded a certain amount of gas of a definite illuminating power. Now, this same coal might, in practice, yield even more than they found in the laboratory test. If they thought this out, they would see why it was. If they were to begin mixing, at an early stage in the manufacture, the poor gas with rich gas coming from fresh charges, they would get a higher illuminating power than if they burnt off single charges alone. He would like to warn them of the common practice of considering coal as being a certain definite invariable sort of article.

In conclusion the lecturer drew attention to some experiments made with a piece of cannel coal 6 inches thick, which was tested for volatile matter down through every inch. The first inch produced 78.8 per cent. of volatile matter; the second, 76.6; the third, 79.4; the fourth, 76.3; the fifth, 69.5; and the sixth, 61.7 per cent.

The second lecture was given on Thursday, when Mr. Wright dealt mainly with the apparatus employed in gas making. He first described the retort setting; dwelling at some length on the combustion of the fuel in the furnace. If they required a useful rule as to the quantity of retort-heating surface that would be necessary to carbouize a certain quantity of coal, they might take it that when the retorts were working at a temperature of 2200° Fahr., they would produce 154 cubic feet of gas per superficial foot of internal heating surface. Of course, if the temperature was lower, a smaller quantity would be produced. In this country the average was 140 or 150 cubic feet of gas per ton per superficial foot of internal heating surface. Speaking of cracked retorts, he said it might seem curious at first that gas could be generated in such retorts. They always had some free carbon in the breaking down of the hydrocarbons; and this free carbon gradually built up a kind of scale which made a surface inside, and filled up the cracks. A retort so covered with carbon would probably lose, through any accidental cracks that there might be, or through the pores, 5 or 6 cubic feet of gas per day per foot of internal heating surface; so that a retort that was well covered with this carbon would, under a pressure of $\frac{1}{4}$ or $\frac{1}{2}$ inch, lose perhaps 5 per cent. of the total quantity of gas produced. When this carbon became objectionable, and was removed, so that the cracks were exposed, the retort might then lose daily 40 or 50 cubic feet of gas per foot of internal surface; in fact, they might lose an almost unlimited quantity of gas according to the pressure. In the normal way of operation, a retort that would produce 10,500 cubic feet when covered with carbon, if recently scaled, might not produce more than 8000 cubic feet out of the same coal at the same temperature. It was usually considered that the carbon formed inside the retort was a great loss to the gas maker; but it really was hardly so. They already had in the tar perhaps 55 per cent. of free solid carbon; and this might just as well be on the sides of the retorts, stopping up the cracks, as anywhere else. In setting retorts, of course, care had to be taken that the heated products of combustion from the coke or other fuel used should come as nearly as possible into contact with the sides of the retorts. Having directed attention to the ascension-pipes, and the great source of trouble they always were from stoppages, he alluded to the cooling of the gas. The gas passed into a collecting-box, or what was known as the hydraulic main; and in a box of this kind, unless the temperature were less than the boiling point of any of the products present in the gas, they would have no condensation, because the temperature would be higher than that at which they would become liquefied. Generally speaking, the temperature of the hydraulic main was less than the boiling point of water; and consequently they brought the products there into a liquid form. The quantity of cooling surface required for a ton of coal varied entirely with the nature of the coal. They could quite understand that a coal that would yield 20 gallons of water per ton would require more cooling than a coal that yielded only 10 gallons per ton. In the case of Newcastle coal, which yielded a comparatively small quantity of water—perhaps 12 gallons to the ton—it might happen that an atmospheric cooling surface of 5 superficial feet per 1000 feet of gas made per day would be sufficient. Derbyshire coal would yield 26 gallons of water per ton of coal; so that gas from this coal would require a larger amount of cooling. In fact, it would need 10 superficial feet of cooling surface per 1000 cubic feet of gas made. Before one could deal with any chemical purification process, the gas had to be treated mechanically, so as to remove as much as possible of the tarry "fog" it contained. Amongst the products that became prominent on the distillation of coal was ammonia, which existed to a considerable extent—to perhaps $\frac{1}{2}$, $\frac{3}{4}$, or 8 lbs. per ton of coal. This ammonia, though valuable in itself, if left in the gas would be a source of considerable nuisance, as it would tend to destroy any brass fittings with which it might afterwards be brought in contact. The ammonia was removed by absorbing it in water. In speaking of the removal of ammonia he wished his hearers to consider the combination between ammonia and water as of an exceedingly feeble character. At a temperature of 112°, it would be hardly possible for minute quantities of ammonia to remain in solution. The question of temperature in connection with the scrubbing of gas had hardly, he thought, received sufficient attention. The lecturer then described the scrubbers and the mode of operation. Supposing they were washing (with water) coal gas containing ammonia, the water at the top of the scrubber would be perfectly free from ammonia; but it would become increasingly charged downwards, until at the bottom 2½ per cent. of ammonia would be found. At this strength of solution of ammonia any gas that stood over it, or was in contact with it, must necessarily contain a certain amount of ammonia; so that it might happen that at a temperature of 50° Fahr. at the bottom of the scrubber, the theoretical conditions would be that they must have not less, perhaps, than 25 grains of ammonia per 100 cubic feet of gas. It was, therefore, evident that if they wished to remove all the ammonia from the gas it could only be done by gradual and persistent

washing, by bringing the gas into contact with clean water—water which did not contain any ammonia. This brought him to the rotary washers, the action of which he explained. Referring to ammoniacal liquor, he said that in the ordinary strength of liquor obtainable on gas-works they had from 20 to 25 per cent. of acids in combination with the ammonia as sulphuretted hydrogen, and the balance as carbonic acid. It would be obvious to them that if by any means they could take the gas liquor and deprive it of its acids, so as to yield a solution of free ammonia, they could again present this liquor to the gas, and take out a further quantity of these acids. In this connection, the lecturer called attention to the Clans process; but remarked that he could not say whether or not it would be a success.

In the third lecture, which was given last night, Mr. Wright dealt further with the subject of purification, as effected in the ordinary way by oxide of iron and lime. Abstracts of this and the fourth lecture (to be delivered this evening) will appear next week.

EUROPEAN GAS COMPANY, LIMITED.

The Annual General Meeting of this Company was held on Monday last week, at the London Offices, No. 11, Austin Friars, E.C.—Mr. H. McLAUCHLAN BACKLER in the chair.

The SECRETARY (Mr. W. Williams) read the notice convening the meeting, and also the following report of the Directors:—

The Directors have to report with deep regret the death, on the 21st of April last, of Mr. William White, the late Chairman of the Company; and they feel that they cannot do better than register, as part of the proceedings of this meeting, the resolution passed by the Board, on being informed of the mournful occurrence. It is as follows:—"The Board desire to express their deep sense of the loss suffered by the Company, and by all the Directors individually, through this lamentable event; also of their high appreciation of his services for nearly 40 years, as a Director, during 20 of which he held the chief office in the Company as Chairman. They wish further to place on record the great regard in which he was held personally, and to convey to the members of his family the sympathy they feel with them under this sad visitation."

Being certain that the shareholders generally will now associate themselves with the Directors in this resolution, they pass on to state that the financial year offers little of importance for comment, with the exception of the success of negotiations which had been in progress for some time, for an extension of the concession at Bolbec. This has now been secured for a period of 20 years; so that the treaty will not expire until the 30th of April, 1926. The Directors have good reason to expect that the new contract thus entered into will greatly tend to the development of the consumption of gas in this industrial locality.

The aggregate increase in the sale of gas at the seven stations is at the rate of a little over 4 per cent. for the year, although there has been but a slight revival from the depression of trade which has so long prevailed.

The cost of coals shows an increase of about £1650, owing principally to octroi duties imposed at Nantes; but this has been more than counterbalanced by the additional price realized for coke at that and other stations during the long winter to which all have been exposed.

The yield from tar was somewhat less than last year; but, on the other hand, the amount realized for ammoniacal products more than compensated for the loss.

Outlay has been kept within reasonable limits; but the demand for additional mains and apparatus required on the works is continuous and must be met, as in all other prosperous gas undertakings. Economy in expenditure does, however, prevail at all the stations; and the amount of capital employed is, therefore, but small.

Under the operation of these circumstances, the Directors are pleased to report that the results of the past financial year have proved favourable, and that they are able to recommend a dividend of 26s. per paid-up share, and in the same proportion on the other two series, payable free of income-tax, on the 1st August next, less the interim dividend of 10s. per share, paid on the 1st of February last.

Provision having been made for this increased dividend, a balance of £1773 19s. 4d. will remain to be added to the reserve, which, the shareholders will remark, is now in great part invested in substantial securities. £10,600 of debentures were paid off, at maturity, during the year; and the amount still outstanding has thereby been reduced to £52,550 repayable within the next four years.

The Board have appointed as their Chairman Mr. Henry McLauchlan Backler, who will also continue to manage the business of the Company generally; and they have filled up the vacancy in the direction by nominating thereto Mr. Henry Chaloner Smith, the largest shareholder in the Company, and otherwise well qualified for the position. The nomination will be proposed for confirmation at the present meeting.

Notice has also been given that two Directors (Henry McLauchlan Backler, Esq., and Henry John Baddeley, Esq.), and both Auditors (F. J. Roan, Esq., and J. Reeson, Esq.) retire from office at this meeting; all, being eligible, will be proposed for re-election.

The CHAIRMAN said he must in the first place express the deep regret he felt at the death of his old friend Mr. White, who was his predecessor in the chair. He had been associated with Mr. White for about 33 years in the affairs of the Company; and he appreciated most thoroughly the qualities which enabled him to be of such vast service to the Company during his long career of 40 years in the offices he held connected with it; and so deeply was his interest centred in the affairs of the Company, that, until the very last, he attended in that room, although he (the Chairman) feared his state of health was not equal to the duties which he voluntarily performed. To within a short time of his death, he was there attending the Board meetings, and that seemed to render his loss more poignant to his colleagues than if he had left them—as there was no doubt he should have done—some time previously. He would now pass on to the affairs of the Company from the business point of view; and, as the report stated, there were not many events for him to mention—the principal being the extension of the Bolbec concession. They had at Bolbec a concession of 18 years to run; and they had obtained 20 years' extension of this—taking it up to 1926. Perhaps it might strike many minds that it was a little early to begin to think about the renewing of a concession which had so long a time before it. This, however, had never been his opinion since he had had any voice in the management of the Company. He had endeavoured, to the best of his ability, to extend the concessions while they had something to give up to the consumers, because if they were to leave it, for (say) two or three years before they commenced negotiations, these two or three years would offer them only a small amount to give up; and consequently they would not obtain any very large concession in return. But when they could give up advantages secured to them for 18 years, then they were entitled to go to the Municipalities and say: "We are now willing to reduce the price of gas for the 18 years which are secured to us. What will you give us in return?" They, of course, said: "What do you want?" We replied: "We want an extension of our concession." These negotiations, like all others, went from point to point. They started from one point, and then proceeded a little further, each giving up something; and in the end they arrived at terms satisfactory to all parties—at all events this was the result of his experience in that Company; and he thought the policy he had always advocated at the Board had proved to be successful for their best interests. Well, they had had a very fair year. As the report stated, the gas-rental had increased by the amount of £9246, which was a little more than 4 per cent. As regarded coals, they had a considerable increase in the cost, owing to the municipal dues at Nantes being imposed upon them—he thought somewhat unfairly; but he did not like to be too hard upon those who were hostile to the Company, because they acted from their point of

view just as they (the Company) acted from theirs. But he did say this—that in the course of the operations of the Company, no unfair dealing of any kind entered into their conduct with others. However, they had paid these duties under protest; and they might consider it advisable to take further proceedings. That, at all events, was in embryo at present. Fortunately, the Municipality, by raising the duty—or rather by imposing it, because there was not any duty on coal previous to that—enabled the Company to sell their coke very much better. This raised the price of coal not only to the Company, but to all the inhabitants of Nantes. The moment the duty was imposed, the Board raised the price of coke, and so recovered the greater portion of what had been taken for Municipal dues on coal. At the other stations they had done very well with regard to coke; and the stocks were almost exhausted at the date of the accounts, March 31. He might say that, within his long experience of the Company, it had several times occurred that stocks had been exhausted in this way; and when such had been the case, and the time of trial had passed away, he had observed in several instances that the increased price had been maintained sometimes for several years. The reason was this—that circumstances which enabled them to raise the price of coals operated some time after the trying season had passed away—that was to say, people grew accustomed to the use of coke as fuel, and they continued to use it when the price was no longer a temptation compared with other fuel. So they had done very well with coke, and this had enabled them to bear the extra cost of the coal. With regard to tar, there was a slight diminution. They had not realized quite so much as they did in the previous year; but they had obtained more from their ammoniacal products. The result was that on these four items of coal, coke, tar, and ammoniacal liquor, there had been a small advantage to the Company during the year. With regard to the increase of profits on which the dividend was now recommended, they arose from the development of business primarily—that was, £2246 of increased rental; and also from economy in expenses, especially on the wear and tear account. Now, he might say truly that, although they had economized very considerably in their charges for wear and tear, they had not done this at the expense of efficiency. The works were kept up as well as they ever had been; and it was the great object of his care that they should continue to be so. He (the Chairman) and Mr. Edward White visited all the stations of the Company in the month of May; and he thought he could speak for Mr. White as well as for himself, and say that they were perfectly satisfied with everything they saw. In former years, he (the Chairman) went round the stations sometimes three or four times a year. They had now, however, got a system of such efficient inspection that he did not think it necessary for him to make more than one visit in the year; and this he intended to continue as long as his strength enabled him to do so. With regard to the dividends, the shareholders would recollect that last year an interim dividend was paid in February of 8s.; and the final dividend of 14s. in August, with a bonus of 2s.—making altogether 24s. during the twelve months. This year they paid in February an interim dividend of 10s.; and the Board now recommended a dividend of 16s.—that was 26s. per fully-paid share, and, of course, in proportion on shares which were only partially paid. This was an increase of 2s. per share, or 1 cent. In addition to this they were able to place a sum—not an unimportant one—to the reserve fund, raising it to a considerable amount. In regard to the debentures, as stated in the report, these were £52,000 odd; and they had been reduced to £47,500 by the repayment at maturity of £5050 on the 1st of this month. Although these debentures would be repayable in the course of the next four years, he could say that he and all the Directors would be very happy if those who held them would claim the money before that. In fact, if they chose to claim it to-morrow for the whole £47,000, the Board would be happy to pay it off; for they had the means to do so. He had very little more to say; but he would mention this—that the position of the Company appeared to be excellent. They had an average of 31 years of their concessions yet to run. There were some, of course, for a much longer period—for 41 years, and the shortest was 18 years; and he hoped this would shortly be increased. With this position and an average tenure of 31 years, their business increasing as they had seen it do during the last year, and with he might say the good will, generally speaking, of the Municipalities—although their nationality was sometimes rather against them—all these features being in their favour, he thought the future of the Company was most promising; and he believed that the system of administration in which their late Chairman evinced such deep interest, and in which he (Mr. Backler) took such a pleasure in seconding him, being continued, as it would be, under the present management, afforded them not only the hope, but a certainty that this prosperity would be continued and increased in the future, notwithstanding any disadvantages they might have to encounter. He concluded by moving—“That the report of the Directors and the statement of accounts now read be received and adopted.”

Mr. H. SOLOMON seconded the motion.

Mr. BEARD said that one of the Company's stations produced a very small amount—that was Boulogne. It yielded only £167. It seemed to him a ridiculous amount compared with the other stations. He also expressed the deep regret he felt, in common, he was sure, with all the shareholders, at the loss of Mr. White. He (Mr. Beard) had been a shareholder for 30 years; and he had always found him a true, sound, and solid friend to the Company. He was glad to see Mr. White's son among the Directors. He had been brought up in a good school; and he believed he would, and did walk in the footsteps of his father. It was quite unnecessary for him to remark upon the pleasure the shareholders experienced in having Mr. Backler to preside over them.

The CHAIRMAN, in reply, said Mr. White explained last year that the Board had been very much disappointed with Boulogne. The sum mentioned was the amount of profit, as was then explained—in excess of 5 per cent., which was credited in the interest account. The Board were disappointed in this way at Boulogne—a fund was voted for a new port, and considerable works were carried on there. The French Government, however, felt the “shoe pinch” them very much; and they were obliged to withdraw the support they had given to the Chamber of Commerce for the erection of these works. At the present time they were stopped entirely. Meanwhile, the Directors were advised that the opening of the new port would lead to a vast amount of business at Boulogne; and they prepared for it accordingly, as they always did—in fact, they would consider it highly imprudent to be left with the possibility of a large consumption overtaking them without the power of supplying it. Therefore the Board constructed works on a larger scale than they needed to have done. This was the fact; and it was not the Board's fault. He had explained the circumstances exactly as they were. There now appeared to be some chance of these works being resumed, as he saw that one of the Ministers had gone to Boulogne a few days ago to look into the matter. If the port was proceeded with, the Directors would hope to find the use of the expenditure they had made on the works; and he believed they would then see a very great difference in their results. He might add that they had changed their Manager at this station; and he thought

they might place more confidence in the present Manager than in his predecessor.

The resolution was then agreed to.

On the motion of the CHAIRMAN, seconded by Mr. SOLOMON, the dividend recommended by the Directors was declared.

The retiring Directors (Mr. Backler and Mr. H. J. Baddeley) were re-elected.

The CHAIRMAN, in thanking the shareholders for his re-election, mentioned that during the 54 years the Company had been in existence, there had been three Chairmen only; and he found this a very encouraging feature; because it gave him an average of 18 years. (Laughter.)

The election of Mr. H. Chaloner Smith to the vacancy in the direction (as notified in the report) was next confirmed.

On the motion of Mr. W. O. DONGSON, seconded by Mr. BEARD, the Auditors (Messrs. F. J. Roan and J. Reeson) were re-elected.

The CHAIRMAN proposed that a vote of thanks be given to the officers.

Mr. SOLOMON, in seconding the motion, observed that he had had an opportunity of judging of their officers' capabilities and industry, and the Shareholders were justified in thanking them for much of the prosperity of the Company.

The CHAIRMAN remarked that he thought the officers were highly worthy of such a recognition of their services. The Board recognized their ability, and valued their integrity. It might, perhaps, be interesting to the shareholders just to mention the fact that the Congress of the French Society of Gas Engineers took place at one of their stations (Boulogne) last month; and great numbers of engineers from all parts of France and elsewhere attended it. It was very successful. Of course, the European Gas Company extended the usual hospitality to them; but at his (the Chairman's) suggestion, The Gas Institute invited all these gentlemen over to England; and a very pleasant time, he believed, they spent, judging from what he was able to hear from them. There were great manifestations of good feeling on all sides. All their own Managers from the European stations attended; and the Board manifested to them the esteem in which they held them, which they could only do by correspondence generally, but which they were able to do personally on this exceptional occasion. The three Anglo-Continental Gas Companies—the European, the Imperial Continental, and the Continental Union—associated with the Union des Gaz, entertained all these gentlemen at the Crystal Palace; and he must say it was as pleasant an evening as they could possibly have desired. He believed the outcome of this would be to promote much good feeling amongst them, and would be beneficial to them as foreigners amongst the French, and would enable them to maintain amicable relations, which otherwise it might have been rather difficult to promote. Therefore he thought this circumstance was a highly favourable one for them and all concerned, whether French or English, or whatever their nationality might be. His own opinion had ever been that the more they could identify themselves with the country in which they carried on their business, the better; and to such an extent had it taken place, that he thought it right to state that there was at present only one Englishman in the service of the Company on the Continent. He thought the French understood thoroughly that the desire of the Board was to express sympathy towards them in every way, placing themselves in an equal position with them; and to employ, as far as they could, people of their own nationality. This had been a very successful policy.

The motion was adopted.

Mr. E. WHITE thanked the shareholders for the kind way in which his father had been referred to, and for the expressions of sympathy which he had received on behalf of the family.

The SECRETARY briefly acknowledged the vote of thanks accorded to the officers; and a vote of thanks to the Board terminated the proceedings.

RIO DE JANEIRO GAS COMPANY, LIMITED.

An Extraordinary General Meeting of this Company was held at the Cannon Street Hotel, last Friday—Mr. LEWIS HOWARD in the chair.

The notice convening the meeting having been taken as read,

The CHAIRMAN said the meeting was not summoned, as the shareholders were aware, by invitation of the Liquidators; but it was simply held in compliance with the Act of Parliament. The stage had now been reached, according to their Solicitor's opinion, for having a meeting to close the liquidation. The Liquidators had no balance-sheet to present later than the final one of Dec. 31, 1887, which was sent out with their circular of the 10th of January last; for their operations since then could be summed up in a few words. The Liquidators had then a cash balance reserved of £520 12s. 2d., which was now reduced to £345 1s. 5d. by the necessary demands for rent, firing, &c., of a small office which they still occupied, and for the salary of a clerk up to last Midsummer, when he left, and by the demand of £75 in settlement of a claim for £236 14s. made upon them by their successors in Rio, which had not been, and indeed could not have been foreseen by the Liquidators. The claim was of a vexatious character, but had some plausibility; and in view of the delay and expenses of the law proceedings, the Liquidators, by the recommendation of their Solicitor, compromised the demand for about one-third of the sum claimed. The whole of the warrants for the return of the share capital—£750,000—were now paid. Of the further and final return warrants, there only remained unpaid £229 17s. 6d. The present cash balance of £345 1s. 5d. would be required for general expenditure to be still incurred. By the direction of the Company's Solicitor, the Liquidators had transferred this sum, together with the £229 17s. 6d.—the amount of the returned warrants still unpaid—to a new account at the London and Westminster Bank, in the joint names of the Liquidators, thereby closing the Liquidators' accounts at that Bank, as necessary according to law. He moved that the report and balance-sheet submitted on the 10th of January be received and adopted.

Mr. J. H. JAMES seconded the motion, which was at once agreed to.

The CHAIRMAN then moved—“That the remaining books, accounts, and documents of the Company and of the Liquidators be destroyed at the end of two years from the date of the meeting.”

Mr. JAMES seconded the motion, which, after a brief discussion, was also carried.

A vote of thanks to the Liquidators concluded the business.

In the course of their report to which the Chairman alluded in his remarks, the Liquidators (Messrs. Howard, J. H. James, G. A. Northover, and W. Baily) state that the Company was placed in liquidation by special resolutions passed and confirmed at general meetings held on Oct. 19 and Nov. 10, 1886, respectively. Since then the following distributions of the Company's assets have been made:—(1) On Dec. 10, 1886, £20 per share; (2) March 22, 1887, £4 5s.; (3, and final) on Dec. 12, 1887, £1 4s. 6d.—making the total distribution £25 9s. 6d. per £20 share. In the final distribution, the gratification, at the rate of 5s. 4d. per share, to the late officers of the Company, on the loss of their appointments, was deducted from the amount of the warrants paid to those shareholders only (the large majority) who kindly authorized the Liquidators to make such deduction; and this has been paid to the ex-officers.

THE TRANSFER OF THE EDINBURGH AND LEITH GAS-WORKS TO THE CORPORATIONS.

At the Meeting of the Edinburgh Town Council last Tuesday—the Lord Provost (Sir J. Clark) presiding—the Town Clerk announced that the Edinburgh and Leith Corporations' Gas Bill had passed both Houses of Parliament, and was now only waiting the Royal Assent. Mr. Colston said he was sure it would be gratifying to the Council generally that this matter had been brought to so satisfactory a conclusion, and that in a few days the gas supply of the city would be vested in a body of public Commissioners, appointed by the Town Councils of Edinburgh and Leith respectively. This result had not been attained without a great amount of labour, forethought, anxiety, deliberate consideration, and consultation, and in some instances firm resolve on the part of those with whom was entrusted the carrying through of this most important measure. It was a great satisfaction to those who were engaged in it that, while the battle raged long and long, not only in Edinburgh, but at Westminster, the ultimate stage was reached on all hands with the most perfect peace, equanimity, and every other good virtue of which human nature could boast. The Town Council was already well acquainted with the nature of the bargain made with the Edinburgh Company, the terms of which the Corporations of Edinburgh and Leith approved. The agreement with the Leith Company, on the other hand, was of a more difficult nature; and while some people, who were imperfectly informed, might hold that as good terms or better might have been obtained at an earlier stage, those who had charge of the business knew better. They knew the difficulties on both sides—on the part of the Directors, who had the interest of their shareholders at heart, on the one hand; and the members of the Corporation, whose sole motive was the interest of the public at large, on the other. Two courses were eventually before them—viz., agreement or arbitration. At the eleventh hour measures were taken to bring the two parties together, to see if an agreement could be arrived at; and he thought it but fair to the Directors of the Leith Company to state that they quite recognized and appreciated the position and responsibility of the representatives of the public when they permitted that it should be a condition of negotiation for settlement that any terms mutually agreed upon should be made subject to the opinion of Mr. Alfred Lass, F.C.A., and Mr. Geo. Livesey, C.E., who were to advise the Joint Committee of the Corporations as to whether or not the terms of purchase were fair and reasonable as between the parties. With this view, it was agreed that when a basis of settlement was arrived at, Mr. Lass should be allowed access to the books and Mr. Livesey to the works of the Company. This eventually took place; and the result was eminently satisfactory. The terms of agreement had already been published. The Joint Committee had the satisfaction of receiving from Mr. Lass and Mr. Livesey a most favourable report, stating that, from an examination of the books, extending over a considerable number of years, and from a thorough inspection of the works, the terms of agreement were fair and reasonable. Both of these gentlemen had sent in written reports—Mr. Lass giving a most elaborate view of the financial part; and so important did the Joint Committee consider these reports, that they on the previous day ordered them to be printed for the information of the Town Councils. Mr. G. W. Stevenson, C.E., in a letter to Mr. Beveridge, the Parliamentary Agent, congratulated the Corporations on having carried through in this session such a Bill—the Gas Bill of the session. "Although," the letter continued, "the terms of purchase of the Leith Company are not so good as those of the Edinburgh Company, they are yet good in themselves; and but for the exceptionally favourable terms on which the Edinburgh Company was bought, not a word could have been said against the terms of the Leith purchase. It was simply not possible to get two such extraordinary bargains as the Edinburgh purchase." Mr. Colston concluded by moving that the Council request the Lord Provost to summon an extraordinary meeting of Council so soon as the Bill obtained Her Majesty's approval, with the view of appointing the Statutory Commissioners under the Act. The Dean of Guild seconded the motion. The Lord Provost, after intimating his readiness to comply with the request, proposed a vote of thanks to Mr. Colston and the Joint Committee for their services in carrying through the negotiations. Mr. Smith Clark disclaimed any acquiescence in the statements made by Mr. Colston as to the goodness of the bargain. (Laughter.) Mr. Colston thanked his Lordship for the motion, and at the same time acknowledged the support which he had received from the members of the Committee.

THE BOLTON CORPORATION AND THE GAS INSTITUTE MEETING.

EXPENSES OF THE CORPORATION GAS OFFICIALS.

At the last Meeting of the Bolton Town Council, exception was taken to an item of £18 18s. 6d. which appeared in the Gas Committee's accounts as "deputation expenses." Mr. Tootill, who was the mouthpiece of the opposition, charged the Chairman of the Gas Committee and the Gas Engineer (Mr. W. Smith) with "displaying a great and grave want of good taste," and a want of consideration for the state of the borough finances, by asking the Committee to send them to the meeting of the Gas Institute, "where many assembled for the express purpose of passing friendly greetings and exchanging opinions one with another." He challenged members of the Council to show that any tangible good had resulted to the borough from such meetings; and asserted that the information acquired at them was simply used for private purposes. Mr. Broughton said he could give many instances in which benefit had accrued to the town from deputations; and one was the excellent purifying house possessed by the Corporation, which was the result of a deputation to the Sheffield meeting. Mr. Haslam said the deputation in question was appointed in accordance with the ordinary custom; and the accounts were brought before the Committee in the same manner. Mr. Greenhalgh altogether took exception to the word "deputation." They were simply representatives of the Gas Committee. Mr. Holt said the Institute was almost exclusively an association of gas engineers; and it was time these deputations, which, in his opinion were useless, were stopped. The Mayor (Alderman Moscrop) said, as Chairman of the Gas Committee for a number of years, he had devoted a great deal of time and attention to the interests of the gas undertaking; but had never gone on any deputation without proper sanction and authority, and then it was for the profit of the Committee and not himself. After the remarks which had been made that morning, neither love nor money would induce him to attend another Gas Institute meeting. Alderman Miles said he was surprised at the kind of encouragement which had that morning been held out to himself, as Chairman of the Committee, and the Gas Engineer. It was a gross libel to make use of the remarks to which Mr. Tootill had given expression. They had simply acted upon a principle which had been adopted for the past twelve years without a single word of exception having been taken. The question had been asked what benefit was derived from the deputations. In answer to that he pointed to the splendid profit which had been made by the gas-works during the past twelve months, and asked if this showed a total want of consideration or watchfulness on the part of the Committee. Instead of having benefited by his visit to the conference, he was out of pocket. The benefits to the town

were incalculable. They had a splendid profit, with gas at a low price and of good quality. He did not wonder at the observations which had been made by the Mayor, and if the Council were not satisfied with what he had done, any one of them was quite welcome to his (Alderman Miles's) position. It was rather singular that, in his first year of chairmanship of the Gas Committee he should be submitted to so much examination; but he did not care that much [snapping his fingers], for anyone who would take a sensible view of the question would see that he had acted in the interests of the town. The proceedings of the Committee were confirmed. In reference to the remark of Mr. Broughton, as to the direct benefit which accrued to the borough from a visit to one of the meetings of The Gas Institute, Alderman Moscrop has since published a statement in which he says that, in attending the meeting at Sheffield, he saw the plan adopted in the erection of a purifying-house there; and when, in the following year, a new house had to be built at the Bolton works, the same design was adopted there. The ground space was limited; and, in accordance with the Sheffield plan, an additional storey was added to the building. They were thereby put in possession of a spacious, lofty, well-ventilated room, containing 980 square yards, which, if treated on a ground-rent at 4d. per yard, 20 years' purchase would represent £326 13s. 4d. The room being so highly elevated above the ground, accomplished its purpose very successfully, and what was more, without being an annoyance to the neighbourhood. Alderman Moscrop, as a further justification for the policy of the Committee, also calls attention to his report summarizing the business done at the meeting at Sheffield; the final paragraph of which contains these remarks *à propos* of the question in dispute:—"Were the present occasion an opportune one, I might refer to other questions brought forward of more general interest, all tending to show that any personal inconvenience or discomfort arising from the visit is compensated by being present at a gathering where to some extent are concentrated the experience and intellectual talent of the gas industries of Great Britain. Incidentally, I may perhaps be allowed to observe further that, besides other places of interest, I visited the chemical works of the Sheffield Gas Company. While there I raised the question how best to convey sulphuric acid from one chamber to another one on a higher level. As the result, and also as an appropriation of the answer, I may confidently, and without egotism, advance the statement that, by a few minor alterations in our gas-works at the Lum Street and Gas Street stations, the purchase of certain appliances may be entirely superseded, and thereby a saving of £100 or thereabouts effected in this small matter alone."

THE MANCHESTER CORPORATION AND THEIR SUBURBAN GAS CONSUMERS.

As was stated in the JOURNAL a few weeks ago, an agitation has been set on foot by some of the Local Boards in the immediate vicinity of Manchester, with a view of obtaining a reduction in the price of gas supplied to their districts by the Corporation of the City. The movement originated with the Gorton Local Board, who invited the neighbouring authorities to a conference. Several of them responded to the invitation; and the meeting recently took place at the offices of the Gorton Board. The other authorities represented were those of Openshaw, Moss Side, Levenshulme, Newton Heath, Withington, and Newton Detached.

Mr. BUCKLEY, of the Gorton Board, who presided, said that for a long time the Board of which he was a member had felt that they were paying too much for the gas supplied for the public lamps and to the ratepayers; and it was thought that if some united pressure were brought to bear upon the Corporation, they might be able to obtain some reduction. All the Boards invited to the conference were present, with the exception of Crumpsall, and they had sent a note cordially agreeing with the object of the meeting.

Mr. HIGGINBOTTOM (Gorton) said, considering the profit made by the Corporation, they ought to treat the out-townships generously; but they were charged 6d. per 1000 cubic feet more than the citizens. It was admitted that the Corporation were making a handsome profit out of the gas undertaking; and it was a question whether they had any right to make such a profit, and whether they ought not to reduce the price of gas in accordance with the profit made, and not dispose of the surplus in other directions. He did not see why any extra rate should be charged in Gorton. The township was contiguous to Manchester, and supplied from the same mains, so that the plea that it cost more to supply gas to Gorton was a fallacy.

Mr. SHARP (Openshaw) asked whether any information could be given as to what the powers of the Corporation were. He was inclined to think the Corporation would treat the matter much in the same way as they had done the sewage question, and make it a leverage for incorporation. Unless the Corporation were exceeding the limit of percentage allowed, he did not think the outside districts would get any reduction.

Mr. PAINTER (Openshaw) considered that the gas question was a byway to the incorporation scheme; and, speaking for his firm (Sir J. Whitworth and Co.), he said they at present paid about £1500 a year for gas, and if incorporated with Manchester they would save money by the reduction in the prices, notwithstanding the fact that the rates would be raised.

Mr. CROFTON (Moss Side) said he knew a firm in Crumpsall who were beginning to make their own gas in consequence of the high price charged by the Corporation.

After a long discussion, it was resolved that a Committee be formed, consisting of one member and the Clerk of each Board represented, with a view of obtaining information as to the power of the Corporation, and to ask for an interview to discuss the matter.

In reference to the position of the Crumpsall Local Board in regard to the matter, it may be mentioned that, when the invitation to the conference was read at a recent meeting, the Chairman (Mr. Prescott) remarked that there was no reason why Manchester should charge the out-townships a differential rate, and pointed to the examples of Salford and Stockport, which do not make an extra charge to suburban consumers. It was decided not to send a representative to the conference, because Gorton, where it was held, was not central and easily accessible.

At a meeting of the Moss Side Local Board held yesterday week, the Clerk submitted a report embodying the result of his investigation of the legal powers of the Manchester Corporation, in regard to the manufacture and supply of gas. Shortly put, the report was to the effect that the Corporation have no statutory monopoly of gas supply, nor have they any statutory authority for making an extra charge for the gas supplied to consumers outside the city. The price is a matter of agreement between producer and consumer, whether in the city or outside it. The Corporation are not limited as to the amount of profit they may make.

NELSON LOCAL BOARD GAS SUPPLY.—The extension of the main from the limits of the Nelson Local Board district to the recently-acquired gas-works at Brierfield was commenced last week. It is understood that the plant at the Bradley Lane works will be sufficient to manufacture gas for the consumption of the whole district; and that the Brierfield works will simply be used for storage purposes.

PAISLEY CORPORATION GAS SUPPLY. THE PRICE OF GAS REDUCED.

The statement of accounts of the Paisley Corporation gas undertaking for the year ending May 28, 1888, has just been brought under the consideration of the Gas Commissioners. In the capital account the gas-works are set down at the value of £102,001 10s. 7d., as at May, 1887. Up to the date of the last balance, there had been borrowed as loans on mortgage, the sum of £58,340; and out of the sinking fund there was paid during the year, £500. The annuities stock amounted to £40,000—the amount redeemed being £39,987 10s.; leaving the small balance of £12 10s. The mortgages redeemed from the sinking fund amounted to £1200, which added to the annuities redeemed, gave a total of £41,187 10s.; and this with the loans on mortgage, &c., made a total of £99,040—thus showing a balance for the year of £296 10s. 7d. Under the head of revenue account, the statement showed that the past year's outlay for gas coal, wages, purifying materials, Manager's salary, &c., amounted to £15,725 4s. 2d. For distribution of gas, including repairs, maintenance, and renewal of pipes, and salaries, there was expended £2090 5s. 10d. The rents, rates, and taxes, amounted to £1987 2s. 6d. For management salaries and general charges there was expended £922 13s. 3d. These, together with various other items, made up a total outlay of £20,731 17s. 10d., which was increased to a grand total of £29,321 16s. 8d. by the balance to profit and loss account of £8589 18s. 9d. From sales of gas supplied by meter there was an income of £24,940 16s. 9d.; and the income from private and public lamps (with £210 15s. written off as irrecoverable) brought up the revenue from this source to £26,100 14s. 3d. The meter-rents and hire of gas-stoves amounted to £319 1s. 9d.; residual products yielded £2400 2s.; and the fee fund £1 18s. 8d.—making in all £29,321 16s. 8d.

At a Special Meeting of the Town Council held on Thursday, the Gas Committee's minutes were submitted, which stated that it had been agreed to devote the net surplus of £5413 17s. 6d., after laying aside sums for the contingent and sinking funds, to certain improvements in the burgh; £200 being voted to the Free Library and Museum, and £200 to the Parks' Committee. The adoption of the accounts, together with these minutes, was formally agreed to. The Commissioners then took up the consideration of the price of gas for the year 1888-9, as a matter which had also been discussed in the Gas Committee.

Mr. WILSON moved that the price be fixed at 2s. 6d. per 1000 cubic feet—a proposal which he had made at the Committee meeting. He said he thought it was reasonable that the gas consumers should know what could be said on both sides as to the policy of fixing the price of gas so as to give a 20 per cent. profit when all expenses had been paid, after the sinking fund, according to the Act of Parliament, and the contingent account, as agreed to by the Commissioners, were provided for; leaving a clear surplus of upwards of £5000 per annum to be spent on public improvements. Several reasons had been given for fixing the price of gas so as to yield large surplus profits; and these he pointed out. He had not the least doubt that their ability to supply such cheap gas was owing to the careful and economical management of the last 18 years, not only by their permanent officials, but by the various gas managers who had taken an interest in it during that time, conducting it on sound business principles—year by year laying aside a sinking fund, year by year extending their operations, and paying their extensions out of revenue. They were now in the position of doing double the business they had in 1870, and while doing so, paying less interest on capital than they then did. They were now doing the largest business with the least charge on capital account of any gas-works in Scotland, so far as his investigations went. The question then came, would it not be wiser to show that they were not behind in everything as a town? They paid far more for road money than any other of the important towns; they paid far higher improvement rates, and far more for drainage than any of them, principally, he believed, because they were much longer in going in for such improvements. He hoped that they would at least beat the whole of those towns in manufacturing good and cheap gas. The price he was asking them to charge would give them a margin of upwards of £1000. If they made it 2s. 9d. per 1000 cubic feet, they would have a profit of £3000; and if they charged 2s. 11d. (which had been agreed to by a majority of the Gas Committee) they would have a profit of £4800, or probably £5000. He was firmly convinced that as they were a commercial community, depending upon public works for their continued prosperity, their wisest policy was to supply both water and gas at the lowest possible price, consistent with keeping both departments in the highest state of efficiency as to plant and everything else connected with the works.

Ex-Bailie MACFARLANE seconded the motion. He held that it was unjust to the gas consumer that the price of gas should be fixed so high that a large surplus might be made, to be voted away to the interest of persons who did not contribute a penny towards making it. The Corporation of Paisley kept up the price of gas at such a figure that a large surplus was bound to be made to vote away for town improvements which had no earthly connection with the Gas Trust. The Provost had said that the result of such a procedure was that the gas consumer whose rental was above £10 suffered most; but he (the speaker) did not admit the statement. If the Provost had given the rateable value of the property held by those gas consumers above £10 rental, and had shown what portion was landlord's and what portion was tenant's, they might have been able to form an opinion; for it was only by comparison that such an opinion could be formed. He then proceeded to lay before the Council some figures which he thought would convince them as to what section of the community suffered most by comparison; and he eventually came to the conclusion that the tenant paid 100 per cent. more by taking the gas surplus to improve the town, than he would require to pay if the improvement rate was a direct tax. This showed, he said, that it was not the largest consumer who suffered most, the real sufferer was the tenant, whether his rental was above or under £10. He further remarked that it seemed to him to be manifestly unjust to make the gas consumer pay more for improving the town than those persons who did not burn any gas—taxing the very persons on whom they depended for the success of the gas-works. Such an idea was so absurd that he was unable to understand how a body of intelligent gentlemen, such as the members of the Town Council, could for a moment entertain it.

Treasurer M'GOWAN moved, as an amendment, that the price be 2s. 10d. per 1000 cubic feet; speaking at some considerable length in favour of his proposal.

Ex-Bailie WEIR seconded the amendment, remarking that gas surpluses in Manchester, Glasgow, and Greenock, were regularly taken for town improvements.

Bailie PATON proposed another amendment, to the effect that the price be 2s. 9d.

Bailie M'KENZIE supported Mr. Wilson's motion; remarking that by disposing of the gas surpluses in the way they did in Paisley, they were putting on the town an additional tax of 4d. to 5d. per £1 of rental.

The ultimate result of the voting was that the price was fixed at 2s. 10d. per 1000 cubic feet, by ten votes against five members who voted for 2s. 6d. per 1000 cubic feet.

THE SOWERBY BRIDGE LOCAL BOARD OF HEALTH AND THEIR LUDDENDEN FOOT GAS-WORKS.

An extraordinary dispute has arisen between the Sowerby Bridge Local Board and Messrs. Whitworth and Co., from whom the Board recently purchased the gas-works situated at Luddenden Foot. Messrs. Whitworth, it appears, decline to pay the price demanded by the Board for gas supplied in the Luddenden Foot district, on the ground that the understanding, when they sold the works, was that the charge should be the same as at Sowerby Bridge. They threaten to resume the manufacture of gas for their own mills if their demand is not complied with; and it is stated that they are already seeking tenders for the works. The matter was referred to at the last meeting of the Board. Mr. Baxendale said the allegations now put forth by Messrs. Whitworth were completely at variance with what really took place. It was distinctly understood that the Luddenden Foot works would be carried on as a separate concern. When the question was opened, Messrs. Whitworth were charging the large consumers 4s. 6d. per 1000 cubic feet, and the general public 5s. (the price had been as high as 6s.). If they found it necessary to charge so much, what reason had they for now wanting their gas at 2s. 4d., for this was what their demand amounted to? They would be sorry to lose them as customers; and if Messrs. Whitworth carried out their threat of withdrawal, it would be in direct opposition to the arrangement made when their works were purchased by the Board. The latter agreed to give the high price put upon the works, on the understanding that they would thus retain Messrs. Whitworth as customers. The Board had lowered the charge, and done all they could, consistently with their reasonable desire that the works should not entail loss, to encourage large consumers. Messrs. Whitworth, who had forfeited all claim to discount on the account due, said they were to be charged Sowerby Bridge price. The nearest approach to any attempt to fix a price by reference to other consumers was when the Chairman of the Board said they should be put on an equal footing with Ripponden. The Clerk said it was certainly never stipulated that Messrs. Whitworth should be charged the same as Sowerby Bridge. £8000 was a lot of money for the works, and Messrs. Whitworth got the best of the bargain. Mr. Baxendale said if Messrs. Whitworth were going to deprive them of their custom, the Board would have to increase the price of gas in the Luddenden Foot district 5d. or perhaps 10d. per 1000 cubic feet, for the works would have to pay their way. The Chairman (Mr. Greenwood) recalled the circumstances under which the extension into the Luddenden Foot district was made, and said certainly the Board were influenced in the purchase of the gas-works by the presumption that Messrs. Whitworth would be good customers. The Board had done all they possibly could to meet them fairly, and must have the money that was due to them. The Clerk was instructed to take steps to recover the amount due.

THE PROCEEDINGS OF THE BOARD OF TRADE UNDER THE ELECTRIC LIGHTING ACT, 1882, IN THE PAST YEAR.

The Board of Trade have lately presented to Parliament a report on their proceedings under the Electric Lighting Act, 1882, during the past year. It states that the only application received by the Board for a Provisional Order was from the South Metropolitan Electric Supply Company, Limited, who proposed to light the whole or portions of the following districts:—The parishes of St. James, Westminster; St. Martin-in-the-Fields; St. George, Hanover Square; and Lambeth; the City of London; the districts of the Strand Board of Works, the St. Giles Board of Works, and the Westminster Board of Works; with certain extra-parochial places. Several of the local authorities of districts comprised within the proposed area of supply objected to the grant of the Order; and, after considering their objections, the Board of Trade eventually decided to restrict the Order to the parishes of St. James, Westminster, and St. Martin-in-the-Fields, with Waterloo Bridge and a small portion of the Victoria Embankment. The application for a further extension of time for the deposit of capital in respect of the Fulham District Electric Lighting Order, 1884, referred to in the previous report (see JOURNAL for July 12, 1887) was not proceeded with. Applications for Licences were received from the Liverpool Electric Supply Company, Limited, for lighting portions of the city of Liverpool; the Kensington Court Electric Lighting Company, Limited, for lighting a portion of the parish of St. Margaret, Westminster; the Corporation of Dublin, for the public lighting of the city; the Wimbledon Local Board, for lighting their district; and the St. James's and Pall Mall Electric Light Company, Limited, for lighting the parish of St. James, Westminster. Of these applications, that relating to Liverpool was granted. The remainder are still under consideration. The Licence to the Kensington Court Electric Lighting Company, Limited, referred to in the previous report, was issued by the Board on Oct. 11, 1887.

THE DUBLIN CORPORATION AND ELECTRIC LIGHTING.

At the Meeting of the Dublin Corporation on Monday last week, Mr. Henley asked the Chairman of the Committee on Electric Lighting what progress had been made; the dates when orders were given to apply for a Licence; if that Licence had been obtained; and, if not, to explain the cause of the delay. He suggested that as the Committee had been sitting from time to time since May 2, 1887, it would be advisable to throw more energy into the matter. Mr. Robinson said that on the date named a Committee was appointed to investigate whether the water power at Island Bridge was sufficient to provide motive force for the electric lighting of thoroughfares; and they were authorized to employ an expert. In October, 1887, a report of the Committee was adopted, that application should be made for a Licence; and this was confirmed by a resolution of the Council on Dec. 12, 1887. On Dec. 28 the Committee instructed the Borough Surveyor to reconsider the specification; and on Feb. 18 last the application was forwarded to the Board of Trade. A meeting had taken place in London between representatives of the Alliance Gas Company and of the Corporation, and a practical agreement had been come to on the matter. Subsequently, a letter was read from the Board of Trade, intimating their intention to proceed with the consideration of the Licence subject to the following remarks:—"As, in deference to the wishes of the Gas Company, the Corporation have agreed to a limit of time being fixed within which the contemplated works should be completed, the Board of Trade will not object to the proposed limit of two years and six months being inserted in the Licence. They are also prepared, as power is sought to supply electricity for public purposes only, to omit the power of transfer now contained in the draft Licence as agreed to by the Corporation. The question of compensation to the Gas Company for public lighting plant thrown out of use by the introduction of electricity is a matter with which the Board of Trade are of opinion they have no power to deal in a Licence; and they are, therefore, unable to insert any provisions for this purpose. With regard to the remaining question in dispute—viz., the area of supply—the Board of Trade do not consider that the reasons advanced by the Gas Company are sufficient to justify the Department in restricting the powers sought by the Corporation for lighting the public streets with electricity to streets

specially named." It was added that, on hearing that the Corporation agreed to the foregoing proposals, the Board of Trade would at once refer the draft Licence to Counsel to settle. Mr. Robinson moved that the assent of the Corporation should be at once notified to the Board of Trade. Mr. Sheehy seconded the motion. Mr. Dennehy (who threatened an application to the Queen's Bench) moved that the matter should be referred to the Finance and Leases Committee, to see whether any expense was incurred. Mr. Doran seconded the amendment. A rather warm discussion followed, in which Mr. Robinson several times moved that the question be put; and it was contended that Mr. Dennehy's motion was not a proper amendment. Eventually it was pointed out that there was not a quorum of members present; and the matter was adjourned.

METROPOLIS WATER SUPPLY.

In the course of their report to the Official Water Examiner for the Metropolis (General A. De Courcy Scott, R.A.) on the composition and quality of daily samples of water supplied to London last month, Messrs. Crookes, Odling, and Tidy say: "During the past month a considerable proportion of the daily samples drawn from the East London Company's mains have been found, when examined by transmitted light, to be slightly turbid, from the presence of finely diffused, suspended mineral matter, attributable to the considerable disturbance of the Company's mains by the provision now being made of a number of new hydrants. With this exception, the character of the entire supply of water to the Metropolis by the seven Companies dependent on the Thames and the Lea has been thoroughly satisfactory. Attention has been called from time to time to the, for the most part, minute seasonal differences in the composition of filtered river water as it is supplied to London. Such a difference is noticeable when comparison is made of the mean results of the examinations conducted during the past month of June, with the closely agreeing mean results of the examinations made in the previous months of April and May. Thus the mean numbers expressing the organic carbon, the oxygen absorbed, and the degree of colour tint of the Thames-derived water supplied during the months of April and May being 0.157, 0.046, and 16.2 respectively; the corresponding numbers for the month of June were found to be 0.147, 0.038, and 11.6 respectively. Moreover, the maximum amount of organic carbon in any one sample examined in April and May being 0.183 part in 100,000 parts of the water, the maximum amount found in any one sample examined during last month was only 0.157 part—a proportion but little removed from the mean, or 0.147 part in 100,000 parts of the water." They add: "During the past quarter of the year we have examined 532 samples of the water furnished by the seven London Companies drawing their supplies from the Thames and the Lea. Notice has been taken of the recent deficiency in clearness of many samples of the East London Company's water. Throughout the quarter, however, the whole of the samples taken from the other six Companies' supplies of water were found to be well-filtered, clear, and bright."

THE WATER ORDERS OF THE PRESENT SESSION.

The Board of Trade have recently issued a memorandum stating the nature of the proposals contained in the Provisional Orders included in the Water Provisional Orders Confirmation Bill—viz., the Herne Bay, Kettering, Mid-Kent, and Wotton Estate Water Orders. The first-named Order is to empower the Herne Bay Water-Works Company to raise £8000 additional capital by shares or stock, and £2000 by loan. The Kettering Order is to empower the Kettering Water-Works Company, Limited, to construct new and additional works in the parish of Kettering. The Mid-Kent Water Order is to give authority to the Mid-Kent Water Company, Limited, to construct and maintain works, and to supply water in the parishes of Snodland, West Malling, Halling, Birling, Ditton, Addington, Leybourne, and Ryarsh, all in Kent; to fix the capital at £18,000 by shares, and £4500 by loan; and to supply water in bulk by agreement within and without the limits of supply. The Wotton Estate Water Order is to empower the Duke of Buckingham and Chandos to construct and maintain water-works, and to supply water in the parishes of Ludgershall, Kingswood, and Woodham, and part of the parish of Brill, all in Buckinghamshire; to fix the capital at £7000, and the amount to be borrowed at £1750; and to authorize the supply of water in bulk by agreement within and without the limits of supply. In the Mid-Kent and Wotton Estate Orders, the rates authorized to be charged for the supply of water for domestic purposes are to be based upon the rateable value of the houses as ascertained by the valuation list; and the usual clauses as to regulations for preventing waste, misuse, or contamination of water, supply of water by measure, and the quantity of land to be taken by agreement, &c., have been inserted; and the Water-Works Clauses Acts, 1847 and 1863, have been incorporated. In the Herne Bay Order the additional capital authorized is required to be offered for sale by auction or tender.

GLASGOW CORPORATION WATER SUPPLY.

The Thirty-third Annual Report of the Glasgow Corporation Water Commissioners has lately been issued, and was adopted at the last meeting of the Council. It first deals with the financial affairs of the Water Trust for the year ended the 31st of May last, and states that the following were the rates assessed and levied during the year:—The domestic water-rates within the city and Royal Burgh of Glasgow, being the limits of compulsory supply, 7d. per £1 of rental, and the public water-rate, within the limits, 1d. per £1 of rental; while the domestic water-rate levied beyond the limits of compulsory supply was the same as that of the previous year, 11d. per £1 of rental. The rates and charges for supplies of water for other than domestic purposes were according to the terms of a table approved of in the spring of last year. From the abstract statement and accounts appended to the report, it is shown that the revenue for the year, including £2416 9s. 3d. from the river supply works, amounted to £163,923 18s. 7d.; in addition to which there was a balance of £6091 6s. 3d.—making a total income of £170,015 4s. 10d. Including the annuities and interest and £4486 6s. 5d. of outlay on the river supply works, the year's expenditure amounted to £118,911 11s. 7d.; so that there was a gross balance of £51,103 13s. 3d., out of which it is intended to carry to the sinking fund account the sum of £37,625 3s. 7d.; thus leaving a balance of £13,478 9s. 8d. to be carried to the credit of the revenue account for the year 1888-9. When the revenue for the past year is compared with that for the year 1886-7, several points of interest crop up. The domestic rate within the municipality yielded during the year £31,379 14s. 2d., which is less than that of 1886-7 to the extent of £4413 6s. 3d. On the other hand, the "outside" domestic water-rate showed an increase of £425 16s. 11½d., on a total revenue of £32,513 1s. 6½d. From the meter supplies within the municipality the amount realized during the year was £39,294 13s. 2d.; showing an increase of £2379 6s. 1d. The revenue for meter supplies outside the municipal area was £14,926 9s. 7d.; being an increase of £1457 9s. 5d. The year's increases amounted to £4998 5s. 4d., as compared with £4547 12s. 10d., which was the amount of the decreases over the year on the various items of revenue; and the total revenue for the year was £163,923 18s. 7d., as against £163,473 6s. 1d.—the difference (an increase) being only £450 12s. 6d.

As already mentioned, the total expenditure over the past financial year was £118,911 11s. 7d.; and the total expenditure during the year 1886-7 was £123,793 10s. There was thus a decrease of £4381 18s. 5d. on the expenditure side of the accounts, which is certainly somewhat remarkable in such a gigantic concern. During the past year there was added to the capital account the sum of £54,615 12s. 1d., of which upwards of £42,000 was on account of three of the new extensive works. Nearly all other items were also on account of new works and extensions. Under the Glasgow Corporation Water-Works Act of 1885, the borrowing power was increased to £3,000,000; and the loans on mortgage, the funded debt issued, Corporation loans, redeemed mortgages, and sinking fund on money borrowed—year 1887-8—represent a sum of £1,813,913 1s. 8d.; so that there is still a balance of unexhausted borrowing power amounting to £1,186,086 18s. 4d. The sinking funds set apart for, and applied in, redemption of mortgages and annuities, in terms of the Water-Works Acts, now amount to £450,999 2s. In view of the unanimous report of the Boundaries Extension Commissioners recommending the enlargement of the Municipality of Glasgow (which if carried into effect, will considerably reduce the domestic revenue), the Water Committee—notwithstanding the large surplus at the credit of the revenue account—have resolved to continue, for the year commencing on the 28th of May last, the same domestic water-rates, public water-rate, and rates and charges for supplies of water for other than domestic purposes, as those of the year 1887-8.

The second portion of the report is devoted to the works. It states that these continue to be maintained in a state of good repair, and that nothing beyond ordinary maintenance appears at present to be required in certain comparatively unimportant exceptions.

The report gives a few facts regarding the water supply of the past year. The quantity of water sent into the city and district during the year ending the 31st of May last, averaged as follows:—

	Gallons per Day.
From the Loch Katrine works	35,206,641
From the Gorbals works	4,367,650
Together	39,574,291
Average for 1886-7	41,376,479
Decrease	1,802,188

The steps taken by the Water Committee during last summer to check the wilful waste and the extravagant use of water have been attended with considerable success; and although the population has increased during the year, as well as the quantity of water sold for trade purposes, it is gratifying to the Committee to find that the average consumption during the past year was notably less than during the previous year. Lastly, the river supply works are statistically dealt with in a brief way. These works continue in a satisfactory state of efficiency. The quantity of water supplied by them during the year averaged 2,419,385 gallons per day; being a decrease of 93,367 gallons per day as compared with the previous year.

THE PROGRESS OF THE VYRNWY WATER-WORKS.

The members of the Water Committee of the Liverpool Corporation have lately made a tour of inspection of the new water-works at Vyrnwy. The party first visited the filter-beds. These are among the largest ever constructed, and are so extensive that three out of four of the beds are sufficient to meet a maximum supply, while the fourth is being cleaned. The filter-beds, being one of the most important parts of the Vyrnwy scheme, will be amongst the earliest portions to be completed. From the reservoir at Vyrnwy, water will be conveyed to Oswestry by two sets of pipes, and thence to Liverpool in one large main upwards of 4 feet in diameter. At Oswestry carriages were hired for the Committee, and a drive was taken across the country to the reservoir; but as it was then evening, nothing further was done. The night was spent in the Engineer's residence on the banks of the intended lake. On the next morning the Committee were driven along the road which marks the boundary of the lake for a distance of about four miles. They subsequently transferred themselves to one of the steam trams in use at the works, and inspected the vast quarries that extend along the hills on one side of the reservoir for a distance of more than two miles. They also went a distance of about 200 yards down the tunnel in which the mains will be carried through the hills. From this point they returned to the "straining tower"—a great structure erected at what is believed will be the stillest portion of the lake, for the purpose of relieving the filter-beds, and preventing any choking of the mains by removing from the water, as it leaves the reservoir, all large floating particles. Obviously the line of mains to Oswestry will need periodical inspection and cleaning; and hence it has been made double. Water will leave the lake by two mains. The first, placed at a certain distance above the bottom of the reservoir, will remove the water after it has reached a given level. It is 4ft. 6in. in diameter. The second, placed at the lowest level, will, if necessary, drain the lake dry. It is 3 feet in diameter, but will only be used in very dry seasons. Lastly, the Committee inspected the embankment, which completes the lake, making it form like a horseshoe. This wonderful piece of constructive engineering is now about complete. Only one or two of the range of archways that have been built above it for the passage of the surplus water have yet to be erected. When the lake reaches its maximum level, the overflow will form one of the most magnificent cascades in the world. Very great confidence is placed by the Committee in the stability of the embankment. The pressure at the base will be 60lbs. per square inch, or 8640lbs. per square foot. To meet this, the embankment at its base is 60 feet thick, and to all appearance is as solid as the surrounding mountains. It may almost be said to be of one piece; for the blocks of stone (many weighing several tons) are cemented together with a mortar composed of special cement, mixed, instead of sand, with the same rock as that of which the embankment has been constructed, but powdered and carefully washed. The interstices have also been filled with gravel of the same material. When the church and village now on the site are removed, the reservoir will be ready for filling. The pipe-lines from Vyrnwy to Halton Castle, Cheshire, on the one side, and from Prescott to Widnes on the other, have already been completed; and provided the connection across the estuary of the Mersey is made without undue delay, the water supply of Liverpool will in April next, or at the latest in May, be assured as long as the city lasts. The Committee will commence filling the reservoir in October next; and in a few months there will be an ample stock, for the capacity of Vyrnwy is 11,000 million gallons, or more than four times that of Rivington. With the average rainfall of the district it can be filled in two months to the height at which the water would commence to flow in the direction of Liverpool.

REDUCTIONS IN PRICE.—The Wandsworth and Putney Gas Company have reduced the price of gas to 2s. 8d. per 1000 cubic feet, as from Midsummer last.—At the annual meeting of the Berwick and Tweedmouth Gas Company last Wednesday, the price of gas was reduced from 4s. 10d. to 4s. 8d. per 1000 cubic feet.—The Directors of the Yeovil Gas Company have reduced the price of gas 2d. per 1000 cubic feet as from the 1st inst., bringing it down to 3s. 7d. net per 1000 cubic feet.

NOTES FROM SCOTLAND.
(FROM OUR EDINBURGH CORRESPONDENT.)

EDINBURGH, *Saturday.*

In this transition period, when the two local Gas Companies have virtually ceased to have an interest in the future of their businesses, and the Corporations of Edinburgh and Leith are considering how they are to conduct the large and responsible trust which will in a few days come into their hands, it is natural that the minds of all who take an interest in the gas industry should turn upon the question of whether the bargain which has been come to is a good or a bad one. This has already been done in the columns of the JOURNAL. On Tuesday last the Town Councils of Edinburgh and Leith both had the felicity of listening to the views of the two men who have piloted them into their present position. In the Leith Council, Bailie Archibald said nothing worthy of notice. It was different in the Edinburgh Council, where Mr. Colston dilated upon the outcome of his labours. Considering that he has not got everything his own way, it is not surprising that he did not say much about the terms of the transfer, but rather sheltered himself behind the views of Mr. Lass and Mr. Livesey on the question of the Leith purchase. Of course, he could not do otherwise than acknowledge that the terms were good—even favourable for the city. Having taken upon myself long ago to urge upon Mr. Colston and his colleagues the propriety of advancing their terms, it is a satisfaction to find that he now virtually coincides with me in the view that at that time they did not offer sufficient. But there is a remark to which I must take exception, when he says: "The agreement with the Leith Company, on the other hand, was of a more difficult nature; and while some, who were imperfectly informed, might hold that as good or better terms might have been obtained at an earlier stage, those who had charge of the business knew better." I do not know what he means by this statement. If the Joint Committee knew then that they could not get these "good or better" terms, why did they not offer the terms which have been now accepted? This knowledge of the Joint Committee was of no value, for they did not act upon it. But I am not aware that anyone ever said that as good or better terms might have been obtained at an earlier stage. All that I am aware of having been advanced against the Joint Committee is that at an earlier stage they wanted too good terms—terms which it was impossible they could get; and that by their refusal to offer worse terms (for the community, better for the Company) they caused needless expenditure. But leaving this side question, it is gratifying to be able to give the opinion of Mr. G. W. Stevenson, C.E., one of the Corporations' advisers, on the Leith purchase. In his letter, read by Mr. Colston, there occurs the passage: "Although the terms of purchase of the Leith Company are not so good as those of the Edinburgh Company, they are yet good in themselves, and but for the exceptionally favourable terms on which the Edinburgh Company was bought, not a word could have been said against the terms of the Leith purchase. It was simply not possible to get two such extraordinary bargains as the Edinburgh purchase." The Corporations are to meet on an early day after the Royal Assent has been given to their Bill, to appoint the Gas Commission. Mr. Colston and his Committee were thanked for their services—a motion with which, although I differed considerably from the Committee on several points, I heartily concur, because the result they have arrived at is eminently satisfactory, bearing out, as it does, the views which I all along urged upon them.

The Berwick and Tweedmouth Gas Company show a good record for the past year. The shareholders met on Wednesday, when it was reported that the total income for the year was £5068 3s. 7d., in which was included £4664 0s. 10d. for gas sold. The expenditure was £3917 9s. 11½d., leaving a net profit of £1150 13s. 7½d. Out of this a dividend of 10 per cent. was declared; and it was agreed to reduce the price of gas from 4s. 10d. to 4s. 8d. per 1000 cubic feet. It may be noted that a year ago the Company made a reduction in the charge for meter-rents. It was stated on Wednesday that the Company's works were now completed, and that the new purifying plant was working most efficiently. The Chairman expressed the belief that next year they would be able, by reason of their new plant, to make a further reduction in the price of gas. The quality of the Company's gas is kept at an average of 80 candles.

The lowering of the price of gas at Alloa is to bear fruit in an increased consumption in the public lamps. The Police Commissioners were contemplating the desirability of paying by meter for the gas they required; but at a meeting on Monday, Mr. Moyes, the Convener of the Lighting Committee, intimated that he would not, on account of the cheapening of the gas, press that proposal. The Commissioners, however, agreed to another part of the motion of which Mr. Moyes had given notice, to reorganize the lighting arrangements of the town by the introduction of additional lamps and the equalizing of the space between those now in use.

The Lauder Gas Company, in the energetic hands of Mr. Turnbull, has, it is reported, had a better year last year than the previous one, but is still unable to pay a dividend. The price of gas is very high—9s. 7d. per 1000 cubic feet.

The Cupar Gas Company have paid a dividend at the rate of 4 per cent.; though the Company have of late years been understood to be in a better position than this figure indicates. Is this the making of a "poor mouth," in view of the dispute with the Town Council about the cost of gas for the public lamps?

The annual meeting of Forres Gas Company was held on Monday. It was stated that the Directors had been considering the question of the price of gas, and now saw their way to recommend a reduction. A dividend at the rate of 7½ per cent. was declared; and it was resolved to reduce the price from 7s. 1d. to 6s. 8d. per 1000 cubic feet.

The affairs of the Edinburgh and District Water Trust are at present attracting a good deal of attention. More than one change has already taken place in the staff of officials; and others are in contemplation, over which there may be some controversy. But the most important question before the Trustees is the necessity for providing an addition to the city water supply. It is already foreseen that, if the great increase of the city since the last supply was brought in from the Moorfoot Hills continues, the present supply will only be equal to the demand for about five years. The Trustees have had their attention turned to two or three sources—the further utilization of the Pentland Hills supply; the bringing in of the Manor Water, a tributary of the Tweed; and the taking up of the scheme, rejected in 1874, of going as far as St. Mary's Loch, in Selkirkshire. To-day the Trustees visited the Manor district to inspect it; and doubtless the other proposals will be similarly dealt with. The Manor water is highly spoken of.

(FROM OUR GLASGOW CORRESPONDENT.)

GLASGOW, *Saturday.*

At a meeting of the Gourrock Burgh Commissioners on Tuesday evening, the gas minutes were submitted, including the annual statement of accounts for the past year. This showed that the total income was £2194, and the expenditure, £1687; thus leaving a surplus of £507. From this there fell to be deducted for interest and repayment of loan, the sum of £471 12s. 3d., leaving a net surplus of £35 7s. 9d. Bailie Lang, Convener of the Gas

Committee, stated that tenders had been received for the supply of coals for the year ending May 15, 1889. With 200 tons on hand, it was found that 800 tons would suffice. There were eleven tenders; the prices ranging, for the various qualities, from 7s. 9d. to 21s. 5d. per ton—the average price being 12s. 4½d. per ton. Bailie Lang said that the contracts which had just been closed were very favourable; and that the Gas Committee hoped next year to be able to recommend a small reduction in the price of gas.

During the last financial year the Selkirk Gaslight Company made 17,306,600 cubic feet of gas; the sales (at 3s. 6½d. per 1000 feet) yielding a profit of £386. The shareholders are receiving a dividend of 10 per cent on the past year's profits.

During the year ending May 31, 1888, the amount of gas made at the works of the Glasgow Corporation Gas Commissioners was 2,705,444,000 cubic feet, as compared with 2,596,470,000 cubic feet in the preceding year. The quantities of gas sold and accounted for during these two years were respectively 2,427,078,000 and 2,285,136,000 cubic feet. During the past year the leakage and unaccounted-for gas was less than that of any former year; the amount being 10·289 per cent., as compared with 11·99 per cent. in the year 1886-87; 11·32 per cent., in the year 1885-86; and 10·66 per cent. in the year 1884-85.

It will be some days yet before the Glasgow Corporation Gas Committee will be able to deliberate upon, and make recommendations in connection with the accounts of the past year of the great undertaking which they have to administer. It may be mentioned, however, that the balancing of the accounts has just been completed; and they seem to indicate that if the allocation of the surplus is made under the various heads in the same way as it was last year, there will still be somewhere about £2000 to the good. It is very likely, therefore, that Bailie Shearer will be unable to obtain the vote of £5000 from the gas profits for the Public Good, which he has been for some time aiming at; and in connection with which he gave notice of motion awhile ago at a meeting of the Town Council.

There has been more firmness during the past week than for a long time previous in the Scotch pig iron warrant market, as there is an improved demand for home consumption, with the consequent reduction of the quantity going into store. There is also a demand for several special brands, the price of which has risen. Scotch warrants touched 38s. 6d. per ton cash yesterday; but the close was 1½d. less. The gains during the week have been: Scotch warrants, 6d. per ton; Cleveland, 4d. per ton; hematite, 5d. per ton.

The local coal trade is showing more favourable signs this week; and coal masters have a more hopeful opinion of the future than they have held for some time.

CURRENT SALES OF GAS PRODUCTS.

LIVERPOOL, *July 21.*

Sulphate of Ammonia.—The market continues to recover; and buyers are paying (with bad grace, of course) the improved values. As much as £11 15s., Hull, and £11 12s. 6d., Leith and Liverpool, have been realized during the week; and there is at the moment remarkably little offering. In fact, everything points to a great strain upon the production in the near future; and there are certainly no stocks now accumulating. Heavy shipments are being made to Germany and Spain; and it almost goes without saying that France and Belgium will "follow suit" presently. There are very few of the requirements filled in the latter countries; and the indications are that sulphate will be used largely. The steady maintenance of nitrate rates, both for present and autumn shipments augurs well for the keeping up of sulphate values; and therefore no decline can at present be foreseen (as it is, nevertheless, by the dealers) when the production again increases after the summer season. With buyers of nitrate cargoes Sept.-Nov. sailing at fully 9s. per cwt., sulphate may be valued at £11 10s. at least for the winter months.

LONDON, *July 21.*

Tar Products.—A better feeling obtains in this market. Benzol has risen; and anthracene is quoted a little higher. Pitch, on the other hand, continues weak; and buyers offer absurd prices for the ensuing season. Prices: Tar, 15s. to 20s. per ton. Benzol, 90 per cent., 2s. 9d. per gallon; 50 per cent., 2s. 4½d. Toluol, 1s. 8d. per gallon. Solvent naphtha, 1s. 2d. per gallon. Crude naphtha, 30 per cent., 1s. per gallon. Light oil, 3½d. per gallon. Creosote, 1½d. per gallon. Pitch, 13s. to 16s. per ton. Carbolic acid (crude), 3s. 5d. per gallon. Cresylic acid, 10d. per gallon. Tar salts, 15s. per ton. Anthracene, 30 per cent., "A" quality, 1s. 4d. per unit; "B" quality, 1s. 2d.

Ammonia Products.—A speculative rise has taken place in sulphate; but, so far as can be seen, there is no substantial back to the rise which has taken place during the week. Prices: Sulphate of ammonia, £11 10s. to £11 15s. per ton, less discount. Gas liquor (5° Twaddell), 8s. per ton, with a rise or fall of 1s. 6d. per degree. Liquor ammonia, 2d. per lb. Carbonate of ammonia, 3½d. per lb. Muriate of ammonia, brown, £18 per ton; white, £28. Sal ammoniac, £30 per ton.

[From the *Chemical Trade Journal*, July 21.]

Sulphate of Ammonia.—The hardening of the market shown in embryo last week has now fairly burst out into bud, though makers should not put too much confidence in the sudden rises in value induced by the machinations of a few speculators. Having bought pretty well at low values, there are some who are extremely anxious for a rapid rise; but it should be remembered that nothing demoralizes the market so much as these extreme fluctuations. Sulphate makers will bave, more and more, to study the markets during the various seasons of the year, and not trust too much to some of those misleading circulars which are occasionally issued by peculiarly interested parties in order to furnish them with the means of feathering their nests. There is a fable of *Æsop's* which seems to us to specially bear upon the earnest solicitations which some speculators profess to have for the sellers of sulphate of ammonia. We will give it next week. Hull price is to-day (Thursday) £11 15s.; while Leith may be stated at £11 12s. 6d. London prices are: Beckton, £11 15s.; and outside makes at £11 15s.

Tar Products.—Benzol has risen during the past week, and a substantial change for the better was visible on Manchester 'Change last Tuesday. On that day the values of 90's and 50/90's might safely have been set at 2s. 11d. and 2s. 5d. respectively; and actual business has been reported at a fraction less than these prices. Solvent naphtha is in good demand at old rates; while crude carbolic (60's) is not value for more than 3s. 4d. The demand for creosote for lighting purposes (the Lucigen Luminator, and other lights) is very good indeed; and it is stated that the Manchester Ship Canal works will soon absorb a very large quantity for their lamps. Anthracene stands at 1s. 1½d. for "B" quality, and 1s. 4d. for "A"; and there is every prospect of these prices being maintained. Pitch is still in an anomalous position; and we can only reiterate what has been said before on this subject. Our London correspondent informs us that 27s. per ton was the price paid for the Salford tar; and further states that he would not be surprised to find prices forced up still further.

SALES OF SHARES.—At the Mart, Tokenhouse Yard, last Wednesday, Messrs. E. Fox and Bonsfield disposed of 50 £10 fully-paid shares in the *West Kent Gas Company* (on which the maximum dividend of 10 per cent. is being paid) at the following prices:—Five at £20 each; 5 at £19 5s.; and 40 at £19. They also sold 25 £10 shares (£4 paid) in the same Company, on which 7 per cent. is being paid, at £6 per share.—At a sale by auction last Friday, small parcels of stock in the *Scarborough Gas Company* were sold at the following prices:—£100 of new ordinary 7 per cent. stock, £106; £80 of 5 per cent. preference stock, £110 15s.; an allotment of new ordinary 7 per cent. stock (£18 paid), £33 5s. The stock was sold with the dividend accrued to June 30 last.

GAS V. OIL AT MALVERN LINK.—The Malvern Link Local Board have decided to light the roads in their district by oil-lamps during the coming winter. This decision has been arrived at in consequence of a dispute with the Malvern Link Gas Company. The Board will not pay for lighting the public lamps what the Gas Company regard as a fair charge. The Company decline to accept the terms proffered by the Local Board. A reference to arbitration was suggested by the Company; but it is said to have been declined. At the last Local Board election, reference was made to the price of gas; and a comparison was instituted between the local charges and those at Worcester, which, as the circumstances of the two places very widely differ, was unfair to the Gas Company.

INCOME-TAX ON GAS-WORKS PROFITS.—A case of considerable interest to the ratepayers of Newcastle-under-Lyme and other corporate towns has just been decided by a Judge in the Queen's Bench Division, sitting in Chambers. Up to the present the Gas Committee of the Town Council have successfully maintained that the sum of £500, annually placed to the credit of the depreciation fund, should be exempt from income-tax. This has been disputed by Mr. Clayton, Surveyor of Taxes, Stoke; and the sum he sought to recover was £15. The Gas Committee were supported in their contention by several large Corporations; and two cases were fought out on the precise point, with success. The Newcastle-under-Lyme Corporation were not represented by Counsel when the case came before the Judge; it having been intimated that such representation would really not be necessary. However, the Attorney-General appeared on the other side; and judgment, with costs, went against the Newcastle Corporation, by default. The effect is that the Gas Committee will have to pay income-tax upon the £500, although no decision is given on the merits of the case at issue; and as the five years during which the depreciation fund was allowed to accumulate have passed, it is understood that the point will not again be raised.

COLNE VALLEY WATER COMPANY.—The report of the Directors of this Company for the half year ending June 30 last, which will be presented at the general meeting of shareholders to be held at the Company's works, at Bushey, on the 3rd prox., states that the total receipts on revenue account amounted to £5037, and the expenditure to £2217, as against £4610 and £2129 respectively during the corresponding period of 1887. Thus the profit carried to dividend and interest account was £2929, as compared with £2481; and the balance of this account, after payment of the 4 per cent. interest on the £65,000 debenture stock and £12,500 preference shares, and transferring another £100 to the reserve account, is £1826. The Directors again propose the payment of a dividend at the rate of 2½ per cent. per annum, less income-tax, which will leave £472 to be carried forward. Since the 30th of June the Directors have sold 8½ acres of the surplus reservoir land at Busley Heath, leaving about 9 acres still in the possession of the Company; which they consider amply sufficient for future requirements. The land was sold by public auction at the Mart, Tokenhouse Yard, and realized £1550, which sum (less the expenses of the sale, &c.) will be credited to capital account; the expenditure on which account last half year was only £491. The disused Harrow Water-Works were offered at the same time, but were not sold.

THE SHEFFIELD CORPORATION WATER-WORKS ACCOUNTS.—The annual abstract of the accounts of the Sheffield Corporation (prepared by the Borough Accountant, Mr. B. Jones) has just been published; and for the first time contains the accounts connected with the water-works undertaking. These show that the liabilities of the Water Company in share capital and debentures, and taken over by the Corporation, amounted to £1,826,000; and that this sum, with an overdraft from the bank of £35,000 (at March 31 last), had been expended in reservoirs, conduits, and other works. The loan transactions of the Corporation in connection with this part of the accounts show that in lieu of the share capital of the Company of £1,336,200, the Corporation have issued annuities amounting in redemption value to £1,549,466. Other accounts show the operations of the water undertaking; distinguishing between the transactions of the Company up to the 25th of March last, and those of the Water Committee. The latter for the quarter ending March 25 shows a trade profit of £797; but this figure, as appeared from a recent debate in the Town Council, is made up under circumstances which admit of a good deal of diversity of opinion. The cost of the water undertaking to the ratepayers is put down at £2,092,689; and the Water Committee have arranged for the additional expenditure of £80,000 or £90,000. No provision appears in the accounts for a sinking fund, which will amount to more than £5000 a year. The total capital account of the Corporation, after the acquisition of the water undertaking, considerably exceeds three millions.

THE CONVEYANCE OF THE VYRNWY WATER TO LIVERPOOL.—On Saturday, the 14th inst., Sir Douglas Galton, the Arbitrator appointed by the Board of Trade to determine the method by which the pipe-line conveying the water from the Vyrnwy shall pass under the River Weaver on its way to Liverpool, resumed the inquiry (which was opened on the 23rd ult.) at the Surveyors' Institution, Westminster. Mr. Pember, Q.C., appeared on behalf of the Liverpool Corporation; Mr. W. H. Higgin, Q.C., for the Weaver Trustees. The latter body urge that a tunnel should be constructed at a considerable depth below the Weaver, in which the pipe-line should be laid; while the Corporation contend that all practical purposes will be served by digging a trench across the river bed and sinking the pipes therein. Further evidence was called on behalf of the Corporation,—viz., Mr. E. B. Ellington, M. Inst. C.E., Engineer to the London, Liverpool, and Hull Hydraulic Power Company, and Mr. J. Quick, M. Inst. C.E., Engineer to the Amsterdam Water-Works—both of whom stated that the propositions of the Corporation would meet all contingencies, and that the scheme sought to be imposed on them by the Weaver Trustees would represent a vast and unnecessary increase of expense. Mr. Higgin then opened the case for the Trustees, arguing that the laying of the pipes across the river bed would be a danger to the navigation, and prevent the Trustees from deepening the river, as they proposed soon to do. Mr. Higgin called two salt manufacturers, having works upon the Weaver, and maintaining large fleets of steamers and barges, who gave evidence in favour of the construction of a tunnel. Mr. Dalo, Accountant to the Weaver Trustees, produced statistics showing the traffic on the river and the revenue of the Trust for several years, and stated that during the last six years the surplus income devoted to the relief of the county rates had been £15,000 a year. Other witnesses were also examined; and the sitting was adjourned till the 26th inst.

THE METROPOLITAN BOARD OF WORKS AND GAS-METER TESTING.—At the meeting of the Metropolitan Board of Works last Friday, the Works Committee reported that the Special Purposes and Sanitary Committee had recommended the Board to take action in Parliament to obtain an amendment of the law to include provision for the testing of the indices attached to gas-meters. The Works Committee, after careful consideration, suggested that the best course to adopt would be to address a communication to the Board of Trade, laying before them all the facts; and they recommended that this should be done, and that the Wandsworth and Putney Gas Company, who had been in communication with them on the matter, should be informed of the present position of the question. This was agreed to.

YEovil GAS COMPANY.—The report of the Directors of this Company to be presented to the shareholders at the annual general meeting next Monday, states that the profit on the year's working will allow of the payment of a dividend of 10 per cent., which the Directors recommend to be declared (free of income-tax), carrying £74 to the reserve fund, and the balance of £911 to next year's account. The reserve fund will then stand at £1500, at which sum it will be closed for the present. There has been a satisfactory increase in the demand for gas for cooking, heating, and motive power, as well as for lighting purposes. Considerable additions to the producing power of the works are now in progress; and important extensions of the distributing mains have been made in various districts. The price of gas has been reduced 2d. per 1000 cubic feet.

PONTEFRAC TOWN SUPPLY.—A special meeting of the Pontefract Town Council was held last Tuesday, to consider the minutes of the Gas and Water Committee. It was recommended that application should be made to the Local Government Board to borrow £25,632 for carrying out the proposed scheme to procure a fresh supply of water from Roall, near Whitfield Bridge. There was much discussion on the subject; and an amendment was proposed and seconded to postpone the question until September, in order, if possible, to induce Knottingley, Featherstone, and other places, to unite in the procuring of a new supply. The Mayor (Alderman Mathers) said the scheme was the best ever proposed for the benefit of the town. At present, in case of fire, £30,000 worth of property might be destroyed, as there was no supply of water in the storage tanks. On being put to the meeting, 13 voted for the original scheme; and 8 for the amendment; so that the Roall scheme is the one that will now be adopted.

THE EXTENSION OF THE BRIGHOUSE GAS-WORKS.—Mr. Arnold Taylor, one of the Inspectors of the Local Government Board, held an inquiry at Brighouse last Tuesday, as to the application of the Brighouse Local Board to borrow £1500, to complete the extension of the gas-works and to purchase sulphate plant. It was explained that in 1884 the Brighouse Local Board obtained a Provisional Order, by which they were empowered to borrow £15,000 for gas-works extension. Of this sum £13,500 had been raised and spent. The Board now intended to manufacture sulphate of ammonia, the building and plant for which would cost £800; £700 would also have to be expended to complete the extensions at the gas-works; and it was for these purposes that the Board asked for sanction to borrow £1500. The Gas Manager (Mr. J. Parkinson) gave particulars of how it was proposed to lay out the money, and said it was estimated that the Board would be able to realize some £200 or £300 a year more by selling sulphate than by disposing of the ammoniacal liquor in its crude state as at present. There was no opposition to the application.

COCKERMOUTH LOCAL BOARD GAS SUPPLY.—At the last meeting of the Cocker-mouth Local Board, Mr. McQuhae, Chairman of the Gas Committee, reported that the Gas Manager (Mr. E. W. Smith) had during the half year ending the 30th of June last made 5,786,000 cubic feet of gas, against 5,517,000 cubic feet made by the Gas Company in the corresponding half of the previous year; showing an increase by the Board's Manager, of 269,700 cubic feet on the half year. The quantity of coal used was 539 tons; being at the rate of 9823 cubic feet of gas per ton of coal carbonized. The Company used about the same quantity of coal. This showed the receipts for the sale of gas at 4s. per 1000 feet, at upwards of £50 more than those received by the Company; whilst the difference in the price of coal was over £100—the coal used by the Company costing about 15s. per ton, and that used by the Board's Manager about 11s. per ton. The quality of the gas was superior; whilst the average candle power for the half year had been 17·27, being 1·27 candle power more than was required by the Act. The sale of residuals had also had a corresponding increase. Since the gas exhibition had been held, the Manager had placed 34 gas-cooking stoves which were giving great satisfaction. The Company during the four months in summer, made less gas than the average of one month in winter; whilst the Board's Manager had made in the two months in summer the average of one month in winter. As the difference in the cost of labour between the winter and summer months was not great, it was clear that an increase in the sale of gas during the summer would show good results at the end of the year.

STOKE-UPON-TRENT GAS SUPPLY.—At the meeting of the Stoke-upon-Trent Town Council last Thursday, the annual abstract of the accounts of the borough, recently presented, were commented upon by Alderman Leason, with special reference to the progress of the gas undertaking. He stated that altogether a sum of £62,700 had been borrowed on the works, but part had been repaid. At the present time they were making yearly at the gas-works 83½ million cubic feet of gas, and selling 77½ millions; so that their loss from leakage was less than 7 per cent., while in the first record after their purchase of the undertaking the leakage was 13½ per cent. It would thus be seen that the Committee and their Manager (Mr. Herman Taplay, Assoc. M. Inst. C.E.) had reduced this very considerably. The residuals last year realized £272 more than in the previous year. The revenue account showed the receipts to be £13,871, while the expenditure was £7723; leaving a gross profit of £6148. Interest on capital, bank commission, &c., absorbed £2338 of this sum; leaving a net profit of £3210. Of the latter sum, £2500 had been handed over to the Council towards the reduction of the rates; leaving the Gas Committee with £700 to the good. Alderman Leason further remarked that he considered their finances were in a satisfactory condition, and that in a short time the adverse balance at the bank would be removed. With regard to the gas undertaking, he thought the inhabitants had no right to more than a fair proportion of the profits, and that the people who made the profits—the consumers—ought to be taken into account. It was, therefore, a matter for consideration whether the time had not arrived for a further reduction in the price of gas. Mr. Sant thought the position of affairs did not justify any reduction. They were now, he said, selling gas as cheaply as any town in the Potteries. It must be borne in mind that there was still a heavy liability on the gas-works; and now that electricity was running gas so close, if the undertaking failed before this liability was cleared off, it would be the ratepayers who would suffer, and not the consumers. A reduction in the price of gas would mean an increase of the district rate; and he did not think they were prepared for that.

THE NORTHERN COAL TRADE.—The demand for steam coals in the north-east of England indicates a large volume of trade, and one which does not as yet show any sign of falling off; but it is at prices which cannot be considered profitable. Best steam coal sells at about 7s. 9d. per ton; and in one or two instances a slight discount is allowed from this rate. Second-class coal is rather more abundant, and about 7s. to 7s. 3d. is the rate. There is a large output of steam coal; and the price is, if anything, a little weaker. Gas coal is slightly more in demand, and every day will increase the sale now, whilst the shipments abroad continue good. There is little doing in household coal; and the demand is reduced by the more seasonable weather. Still some of the land-sale collieries ask 9s. per ton for best household coal at the pit. For export the price is much lower.

BOLTON CORPORATION GAS SUPPLY.—At the last meeting of the Bolton Town Council, the members were presented with a copy of the Borough Treasurer's accounts for the year ending March 25 last. According to the statement of the Chairman of the Gas Committee (Alderman Miles), as to the operation of this branch of the Corporation work, there is the large sum of £12,436 carried to the reserve fund (one-third more than the Committee in 1874 thought would ever be necessary); and £11,500 is transferred in aid of the district rates. Amongst other items of income, a sum of £7179 6s. 10d. is noticeable from public lamps. This item appears for the first time. The residual products returned £14,964; the sulphate of ammonia manufactured forming the larger proportion. In the gas-works capital account, which is more clearly and fully set forth than hitherto, the sum of £30,000 is written off for depreciation of works not covered by expenditure on renewals.

THE WIGAN CORPORATION DEBT.—At the last meeting of the Wigan Town Council, Mr. Lamb, the Chairman of the Finance Committee, submitted proposals for the conversion of the Corporation stock. The stock bears interest varying from 4½ to 3½ per cent. (a very small proportion being at the latter figure), and is redeemable by annual drawings by lot. The gas loan is represented at £177,085, repayable in 60 years; and the other loans at £131,000, repayable in 80 years—making a total of debenture bonds of upwards of £308,000. The Committee's proposal is to convert the whole of the stock to a uniform basis, bearing interest at 3 per cent.; and with a view to bring about the change, they recommend that there shall be offered for 3½ per cent. stock a premium of £8; 4 per cent., £8; and 4½ per cent., £10. They also propose to remove the liability to be drawn by lot, and to guarantee that the stock should not be further interfered with for ten years except at the option of the holders, but that it should afterwards be redeemable upon six months' notice being given. The Council sanctioned the scheme.

MONTROSE GAS COMPANY.—The annual general meeting of this Company was held on Wednesday last—Ex-Provost Reid in the chair. The Solicitor (Mr. Dickson) read the report for the past financial year, which showed that the total income (including £1279 from the previous year) was about £6593 9s. 4d., and the expenditure £4071 17s. 2d.—showing a surplus of £2521 12s. 2d., or, deducting the balance carried forward, a profit of £1242 1s. 2d. It was agreed to pay the usual dividend of £3 per share, to meet which, however, about £257 will have to be taken from the reserve fund. It appeared from Mr. Dickson's statement, that the consumption of gas in the town had been gradually decreasing for three years past; and that the falling off in the income was chiefly due to the depreciation in the value of residual products, which in 1886 realized £474, in the following year £464, and last year only £185 11s. 5d. Had they fetched their previous price, instead of a deficiency, there would have been a small surplus. The Chairman thought, in view of the depressed state of the town, the shareholders might congratulate themselves on the position in which the Company stood. In moving the reappointment of Mr. Hall as Manager of the works, the Chairman paid a high compliment to him for the able manner in which he had discharged his duties; and stated that the Directors had agreed to recommend that his salary be increased by £25 per annum. The Chairman moved accordingly; and Mr. J. Johnston seconded the motion. Mr. Deans moved, as an amendment, that, in view of the fact that the income of the Company was falling off, and of the slight prospect of the trade of the town improving, no increase be given. On a division, the motion was carried by a large majority. Mr. A. Melville Watt was re-elected as Secretary and Treasurer; and a vote of thanks to the Chairman concluded the proceedings.

* Station closed for cleaning.

SULPHURETTED HYDROGEN.—None on any occasion.

PRESSURE.—In excess on all occasions.

Note.—The standard illuminating power for common gas in the Metropolis is 16 sperm candles, and for cannel gas 20 sperm candles. Sulphur not to exceed 17 grains in 100 cubic feet of gas; ammonia not to exceed 4 grains in 100 cubic feet of gas. Pressure between sunset and midnight to be equal to a column of 1 inch of water; between midnight and sunset, 6-10ths of an inch.

GWYNNE & BEALE'S PATENT GAS EXHAUSTERS AND ENGINES.

PLEASE ADDRESS IN FULL—

GWYNNE & CO.,ADDRESS FOR TELEGRAMS:
"GWYNNEGRAM LONDON."

HYDRAULIC AND GAS ENGINEERS, ESSEX STREET WORKS, VICTORIA EMBANKMENT, LONDON, W.C., ENGLAND.

TELEPHONE No. 2008.

Thirty-three Medals at all the Great International Exhibitions have been awarded to GWYNNE & Co. for Gas Exhausters, &c.

Only Medal at the Liverpool International Exhibition, 1886, for Centrifugal Pumping Engines.

They have never sought to make price the chief consideration, but to produce Machinery of the very highest quality.

The result is that in every instance their work is giving the fullest satisfaction.

They have completed Exhausters to the extent of 24,000,000 cubic feet passed per hour, which are giving unqualified satisfaction in work, and can be referred to.

ONLY 75 REVOLUTIONS PER MINUTE.

The above Engraving shows Two Engines driving Four GWYNNE & CO.'S PATENT NON-FLUCTUATING EXHAUSTERS, to pass 200,000 cubic feet per hour (without the slightest oscillation), at the EFFINGHAM STREET GAS-WORKS, SHEFFIELD.

Can be made, when desired, on their New Patent principle to pass Gas without the slightest oscillation or variation in pressure.

NO OTHER MAKER CAN DO THIS.

GAS VALVES, VACUUM GOVERNORS, REGULATORS, PUMPS, &c., &c.

Catalogues and Testimonials on application at the above address.

OXIDE OF IRON.

THE Gas Purification and Chemical Company, Limited, advise their friends that their only representatives for the Sale of Oxide are Mr. Andrew Stephenson and such Sub-Agents as may be accredited from the Head Office. They further state that the royalties possessed by them extend over an area of more than 350,000 acres, and are held for a long term of years. They employ their own overseers and labourers, and there are no intermediate profits between them and the consumer.

Address 161 to 163, Palmerston Buildings, Old Broad Street, LONDON, E.C.

JOHN WM. O'NEILL,
Managing Director.

ANDREW STEPHENSON, Agent for the Gas Purification and Chemical Company, Limited, 158, Palmerston Buildings, Old Broad Street, LONDON, E.C.

CANNEL COAL, &c.

JOHN ROMANS & SON, EDINBURGH. Gas Engineers, supply all the most approved SCOTISH CANNELS; also FIRE-CLAY GOODS, CAST-IRON PIPES, and other APPARATUS for GAS AND WATER WORKS.

Prices, &c., will be forwarded on application to No. 80, St. Andrew Square, EDINBURGH, } SCOTLAND.
No. 54, BERNARD STREET, LEITH, }

SULPHURIC ACID, B.O.V., for Sulphate of Ammonia Making. Guaranteed clear, of full strength, and to produce a fine white-coloured salt. Delivered in carboys or railway tank waggons.

For prices and terms address BALE, BAKER, and Co., 120 & 121, Newgate Street, LONDON.

CROWTHER BROTHERS solicit a trial of their IMPROVED SYSTEM OF RETORT SETTING. Can guarantee them to heat well, and the bottom Retorts to Carbonize as much Coal as those at the top. Constructed to burn Tar or Coke. Can be altered in a few minutes.

For particulars, write to 384, Mile End Road, LONDON, E.

GAS-WORKS of any magnitude leased, at premiums ranging from 5 to 10 per cent., according to the size of the Works. Gas-Works erected or re-modelled upon the most modern principles.

Address GEORGE WELLER, Gas Engineer, St. Ives Cornwall.

A YOUNG Man (aged 22), the Son of a Gas Manager, will be glad to meet with an appointment as CLERK, COLLECTOR, or MANAGER for Gas-Works at home or abroad.

Good references; and security given.
Address No. 1017, care of Mr. King, 11, Bolt Court, FLEET STREET, E.C.

A MARRIED Man, 31 years of age, seeks an Engagement as WORKING MANAGER, or the charge of Engines and Exhausters. Now Manager of small works. Can have good testimonials.
Apply to C. P. Mr. Smith, Ratlington Street, Chatham, near Canterbury, Kent.

DRAUGHTSMAN Wanted, experienced in Gas Apparatus, Structural Ironwork, and Quantities, by leading firm of Gas-Works Contractors. State salary, experience, and give references to No. 165, care of Mr. King, 11, Bolt Court, FLEET STREET, E.C.

RETORT-SETTER Wanted, at once; thoroughly practical.
Apply, stating wages and giving reference, to CROWTHER BROTHERS, 384, Mile End Road, LONDON, E.

TIMMIS & CO., of STOURBRIDGE

Make only the best quality of FIRE-CLAY RETORTS, BRICKS, TILES, & LUMPS. Also SPECIAL SILICA BRICKS, to stand great heats. All descriptions kept in Stock.

For Prices apply to JAMES LAWRIE and Co., 63, Old Broad Street, E.C., Sole Agents for London and District. Telegraphic Address: "EIRWAL, LONDON."

ALEX. WRIGHT & Co., 55, 55a, and 56, MILLBANK STREET, LONDON, S.W.

[Telegraphic Address: "PRECISION LONDON."] Makers of Wet and Dry Gas-Meters, Station Meters and Governors, Photometers, and Gas-Testing Apparatus, Test Gasholders and Meters, Registering and other Gauges, &c., &c.

* * See Advertisement on Page III. of the Wrapper of last week's issue.

W. C. HOLMES & Co., Huddersfield,

AND 80, CANNON STREET, LONDON, Contractors for Gas-Works complete, Makers of Gasholders, Purifiers, Scrubbers, Condensers, Retort Fittings, &c., Improved Valves, Engines, and Exhausters. A'so for Collingwood's Regenerative Retort-Settings.

* * See Advertisement p. 182 of this week's issue. Cablegrams: "Ignitor London." Telegrams: "Holmes Huddersfield."

"EXCELSIOR" TAR-BURNER.

TAR worth 30s. per ton for Burning. Come and see and believe, or send for Burners complete, with Instructive and Descriptive Pamphlet, 16s. 6d.

Estimates given for Fixing and Starting, and satisfactory working guaranteed on application to THOS. BURTONSHAW, Gas-Works, CHIPPING NORTON.

WANTED, at once, a Gas Exhauster; capacity, 10,000 or 15,000 feet per hour. Must be in good condition.

Apply to the SECRETARY, Gas-Works, NUNEATON.

WANTED, a Situation by a Practical

GAS-FITTER, as Leading Hand or otherwise. Well up at Index Taking, Stoves, Services, &c. Good references.

Address J. WHITE, 52, Henshaw Street, Walworth, LONDON, S.E.

WANTED, for the Rochford Gas Com-

pany (1500 Inhabitants), a Man competent to undertake the duties of WORKING MANAGER. House and firing provided.

Apply, stating age, qualifications, and wages required, to GEO. WOOD, Secretary to the Gas Company, Rochford, Essex.

WANTED, 5000 feet per hour Exhauster

and ENGINE, with 6-inch connecting-pipes. Also Small HORIZONTAL BOILER. Must all be in good working order.

Apply by letter to No. 1636, care of Mr. King, 11, Bolt Court, FLEET STREET, E.C.

WAGGON-TANKS.

WANTED, Second-hand Railway Tank-WAGGONS, in good condition.

Full particulars and prices to the SHARON CHEMICAL COMPANY, DERRY.

TO GAS ENGINEERING FIRMS AND COLLIERY PROPRIETORS.

WANTED, by a Consulting Gas Engineer, the LONDON AGENCY for any good Firm. The Advertiser has a good Gas Connection.

Address, in first instance, No. 1634, care of Mr. King, 11, Bolt Court, FLEET STREET, E.C.

IRISH BOG ORE OXIDE OF IRON.

GAS PURIFICATION.

BALE, BAKER, & CO., direct Importers from Ireland. Sample and Price on application. Spent Oxide and Sulphate of Ammonia purchased. 120 and 121, NEWGATE STREET, LONDON, E.C.

TUBES.

FOR Gas, Steam, and Water; Galvanized, White Enamelled, and Hydraulic Tubes and Coils. JOHN SPENCER, Globe Tube Works, WENNESBURY, and 14, Great St. Thomas Apostle, LONDON.

SULPHURIC ACID.

JOHN NICHOLSON & SONS, Chemical Works, LEEDS, specially produce this ACID for making SULPHATE OF AMMONIA of high quality and colour. Highest References and all particulars supplied on application.

OLPHERT'S Natural Oxide of Iron— SUPERIOR IRISH BOG ORE (obtained from the finest estates in Ireland)—is now VERY LARGELY and SUCCESSFULLY USED for Gas Purification.

The sole representative for selling this Oxide is A. C. FRASER (late Gas Engineer at Bolton). Bridgewater Chambers, Brown Street, MANCHESTER.

SULPHURIC ACID.

HUGH WALLACE & CO., Chemical Manufacturers (the old-established firm), supply the above, which is specially adapted for making White Sulphate of Ammonia. The latter purchased in any quantities at highest market prices, or contracts for the year.

For price and terms apply Botolph House, Eastcheap, LONDON, E.C.

BRISTOL UNITED GASLIGHT COMPANY.

THE Directors of the Bristol United Gaslight Company are about to appoint a CHEMIST at each of their Avon Street, Canons' Marsh, and Stapleton Road Works, and invite applications for the appointments.

The candidates selected will be required to devote the whole of their time to the duties of their respective offices, and must be capable of making the usual tests and analyses required in Gas Manufacture.

The commencing salary in each case will be £80 per annum.

Personal canvassing will be a disqualification. Applications with copies of testimonials must be sent in, addressed to the Chairman of the Company, not later than Ten a.m. on Monday, the 30th of July prox.

JAS. V. GREEN, Secretary.
Gaslight Offices, Canons' Marsh, Bristol,
June 21, 1888.

BRISTOL UNITED GASLIGHT COMPANY.

THE Directors of the Bristol United Gaslight Company are about to appoint two RESIDENT GAS ENGINEERS, to take charge of their Avon Street and Stapleton Road Works respectively, and invite applications for the appointments.

The candidates selected will be required to reside on the premises—where free House with Gas, Coal, and Water will be provided—and to devote the whole of their time to the duties of their respective offices. They must have had a thoroughly practical training, and be conversant with Gas Engineering in all its branches.

The salary in each case will be £300 per annum. Personal canvassing will be a disqualification.

Applications with copies of testimonials must be sent in, addressed to the Chairman of the Company, not later than Ten a.m. on Monday, the 30th of July prox.

JAS. V. GREEN, Secretary.
Gaslight Offices, Canons' Marsh, Bristol,
June 21, 1888.

NOTICE TO SUBSCRIBERS
AS TO PAYMENT OF SUBSCRIPTIONS IN ADVANCE.

Subscribers who desire to avail themselves of the reduction in the Subscription to the JOURNAL by paying in advance for the second half of the year 1888, are reminded that this can only be done during the present month

The Subscription is at the rate of 21s. a year paid in advance, or 25s. if credit be taken.

THE JOURNAL OF GAS LIGHTING,
WATER SUPPLY, & SANITARY IMPROVEMENT.

TUESDAY, JULY 31, 1888.

GASHOLDERS WITHOUT GUIDE-FRAMING.

THE account which will be found in another column, of the raising of a three-lift gasholder at the Rotherhithe station of the South Metropolitan Gas Company, without extension of the guide-framing beyond the height of the second lift, is a noteworthy evidence of a striking advance in gasholder construction. The question of the possibility of dispensing with the upper portion of the guide-framing of gasholders has been discussed in the columns of the JOURNAL upon numerous

occasions, and formed the subject of a paper read before The Gas Institute at Glasgow last year; but it is only natural that the minds of the practical men who are fond of declaring that "an ounce of fact is worth a pound of theory" should be struck with this Rotherhithe experiment, as they never would be by any number of papers and articles in engineering publications. We shall not be far wrong, therefore, in assuming that the news of the successful inflation of this—according to old ideas on the subject—imperfectly framed holder, will bring the matter forward again in the thoughts of gas engineers with a freshness and force that could not be imparted to it by any other means. Mr. George Livesey deserves to be congratulated on the success of his bold experiment, which, it is not too much to say, no other man would have attempted upon such a large scale. It is one thing to profess acceptance of a theorem in applied mathematics, when the result is merely stated in a technical communication to a professional society, or to confess that there "may be something" in a well-written article stating novel views of a matter of engineering practice that has always been treated in some traditional fashion. It is an altogether different affair to carry out one's convictions by sending up a 150-foot gasholder into the air without that support which tradition would declare to be necessary to prevent overturning. In the informal conversational discussion that followed the reading of Mr. Webber's paper at Glasgow, and in which, as is usual, men's real opinions were more candidly confessed than in the formal debate, a remark commonly made was: "It may be all right to guide a gasholder from the bottom instead of in the ordinary way, but I should like to see it tried by somebody else first." This is a cheap kind of criticism which is worth nothing; and, fortunately for gas engineering, it is a kind of criticism that has never been favoured by Mr. Livesey. He has now added one more to the proofs of daring originality which he has shown during his career. It cannot but be regarded as deplorable that, while the most authoritative discussion of this particular point in gasholder construction took place at last year's Gas Institute meeting, the members will not have an opportunity for considering the practical proof of the principles there advanced, since Mr. Livesey has now withdrawn from the Institute, and nobody will remain to explain his work.

It will be advisable to recapitulate a little, in order that the full significance of this Rotherhithe experiment may be realized. Up to last year it was generally accepted that the overturning force of the wind, exerted against a gasholder from one direction, tended to push the holder along a horizontal plane, and could be equally divided among the number of guide-rollers brought into play, irrespective of whether these happened to be on the bottom, middle, or top of the holder. This is, briefly stated, the old theory of gasholder stability. Such was the view taken by Mr. Corbet Woodall last year, when discussing Mr. Webber's paper. He said that "the pressure would be evenly divided between the top and bottom rollers on the leeward side. . . . He maintained that beyond doubt the effect of a strong wind upon a holder, . . . if guided in the ordinary manner, would be to "push it upright against the leeward guides." Mr. Hunt prudently decided to await the issue of the projected Rotherhithe experiment before declaring himself; and Mr. Foulis thought that wind does push a holder along a horizontal plane, and spoke of a holder as "fairly resting upon both top and bottom guides." If, however, a holder does so rest upon top guides, what would happen when this support is taken away? By the old theory, destruction through overturning; by the new, nothing at all. The Rotherhithe example answers this question conclusively.

Thus it will be seen that the new departure is a radical one, and contradicts the fundamental assumption of the old theory. The theory must accordingly be reconstructed; and in what direction if not in that already indicated? The extent to which gasholder guide-framing can be cut down becomes, therefore, a question of degree; and the best way to settle the problem in its new phase is by direct experiment. The opportunity may perhaps be presented in connection with demolition; if not with construction. It would not be much trouble, when a holder is to be broken up, to ascertain the minimum conditions of its stability by progressively removing the guide-framing first. The chief objection to this proposal is that when holders come to be demolished they are generally so old and rickety that no useful purpose could be served by experimenting with them. Yet there may be occasions—as when a small holder in good condition is removed to make room for a larger one—when an experiment of this

order could be satisfactorily instituted. It would be necessary, of course, in such a case, to start with a proper understanding of what is desired to be learnt by the experiment, and then to carry it out in a proper manner.

It is remarkable, in connection with the Rotherhithe experiment, that the behaviour of the holder was not affected in any way by the wind. It has been assumed, in all discussions of this subject, that the wind is the principal overturning agent that must be reckoned with. This example shows, however, that the wind has ordinarily little or no effect on the elements of stability of a gasholder. In a great storm, of course, the case would be different; but it would perhaps not be an exaggeration to say that a holder that is stable in fine weather would be stable in a storm. We do not speak here of the effect of weaknesses of materials (which might be developed with disastrous results during the extra strain of a gale), but of the ordinary statical conditions of a holder, regarded as an unstable vessel maintained in equilibrium by external supports. If it will stand by these means in fine weather, it will stand in any weather, because the influence of its own weight and form in creating instability is greater than anything the wind can bring to bear. Wind is a casual and irregular overturning force; but a gasholder always contains in its constitution the strongest influences working for its own destruction. Wind or no wind, a gasholder will fall if not sufficiently supported. The problem now is to show how the needful support may be most economically and efficiently supplied. The Rotherhithe holder works without top supports: How much else could be safely dispensed with?

THE MEETING OF THE NORTH BRITISH GAS MANAGERS' ASSOCIATION.

The North British Association of Gas Managers met in Glasgow last week, under the presidency of Mr. David Terrace, who delivered a sensible, unpretentious address. Mr. Terrace is greatly in favour of regenerator firing for gas-retorts, to which he rightly ascribes high effectiveness in the matter of increasing output without extending retort-bench area. There can be no doubt that in many places the adoption of this system has increased the productiveness of retort-houses by 50 per cent. and upwards—an important consideration, especially in crowded neighbourhoods and wherever land is not readily obtainable. Mr. Terrace made some wise remarks on the subject of the comparative values of gases of different illuminating power, especially when oil gas is compared with coal gas; and also on consumers' burners, to which he has apparently devoted a considerable amount of study. The most important paper submitted to the meeting was Mr. Geo. R. Hislop's report upon the best standard burner for Scotch gas. Mr. Hislop has taken great pains with his subject, and has succeeded in producing a statement of lasting interest. Starting from the datum that the union-jet burner is the standard for photo-metrically testing Scotch cannel gas, with a regulation pressure of 5-10ths at the point of combustion, Mr. Hislop hit upon the notion that a great deal depends upon the angle at which the convergent holes of these burners are drilled. The details of his experiments, as given in his paper, are sufficient testimony that he was on the right track in this research. He claims to have discovered that, while a burner of this description may fulfil the requirements of the law, it will not give a satisfactory flame with the holes drilled at the usual angle, unless the gas is consumed at a pressure far below that specified in most Acts of Parliament. He establishes the important generality that the richer the gas the greater must be the angle between the convergent jets. Beginning at the very bottom of the scale with the poorest imaginable gas—say, 5 candles per 5 cubic feet per hour—a round jet would be the best for burning it; and this flame would be produced by two parallel jets placed side by side. For every higher quality of gas recognized by gas makers, the two holes should converge more and more, until with gas of about 32½ candles they would stand at an angle of 45°, which would at the legal pressure give a flame 3½ inches wide and 3¼ inches high. Mr. Hislop deserves the thanks of all who are interested in the practical problem of gas consumption for his masterly statement of the secret of the construction of union-jet burners. He has certainly worthily discharged the obligation placed upon him by the Association to discover the best standard burner for Scotch gas; and it may be expected that union-jet burners drilled to different angles, and marked for the quality of gas for which they are best fitted, will henceforth become stock articles of trade. It is seldom one sees an inquiry sent to a Committee answered so promptly and fairly as this has been by Mr. Hislop. It

should be remarked that his North British colleagues have signified their appreciation of Mr. Hislop by making him their President for the third time; and that next year's meeting is to be held at Dunfermline.

THE AFFAIRS OF THE MANCHESTER CORPORATION GAS DEPARTMENT.

The accounts of the Manchester Corporation Gas Department for the year ending March 31 last are to be presented to the Town Council to-morrow, with the usual report of the Committee on their administration of the undertaking and its returns for the year ending March 31 last. In their report, which will be found elsewhere, the Committee claim that from the 293,348 tons of coal and cannel carbonized they have obtained an average production of 10,383 cubic feet of 19·96 candle gas per ton. If this is a reliable statement—that is to say, if the average is a fair one—this is very good working. The Committee draw attention to the improvement in carbonizing results as compared with previous years, which they ascribe to the introduction of better appliances in the works. The consumption of gas in the district served by the Corporation mains is almost stationary, however; the increase for the year having been only 0·85 per cent. With regard to profit, it is stated that after writing off £33,623 for depreciation, there remains a balance of £106,072. Out of this come the charge for interest, £29,832; wages and repairs for street lighting, £8528; sinking fund, £26,454; and £23,331 paid into the city treasury during the year. These payments leave a balance of £17,925, which has been applied to the reduction of the adverse balance of the profit and loss account for the past two or three years. There is in these facts plenty of matter for warm debate at the Council meeting. A strong appeal will be made for a substantial reduction in the price of gas; and another will in all probability be preferred for an increased subsidy in aid of the city funds. It is unnecessary to say to which cause we incline. The consumers of Manchester gas have suffered long, and surely they are entitled to some relief at last. When we commented upon the preceding report of the Manchester Corporation Gas Committee, we were constrained to animadvert somewhat strongly upon the terms of the report of the Official Gas Examiner, Mr. John Leigh, the Medical Officer of Health for the city. This year Mr. Leigh has been a little more explicit, and has wisely dropped his former practice of apologizing for the shortcomings of the Committee. He states that sulphuretted hydrogen was present in the city gas on 18 days. What would the Corporation have said if this dirty gas had been sent out by a Company? Carbonic acid to the amount of rather under 3 per cent. was nominally present in the gas—thus robbing the consumers of some thousands of pounds' worth of illuminating power; and the average dose of sulphur was 37·34 grains per 100 cubic feet. There is in all this nothing very creditable to the Manchester Corporation Gas Committee. Selling bad gas is not, unfortunately, the only questionable custom into which this representative Gas-Works Committee have fallen. Their revenue account for the year sets out in detail the salaries paid to their officers, from the Superintendent and the principal Station Manager down to the clerks in the various departments. We say nothing at present of the totally inadequate remuneration paid to the men who are mainly responsible for the profitable working of the undertaking; but what is to be thought of the administrators of a gas undertaking with a revenue of £442,362 a year, who pay their Chief Bookkeeper the magnificent sum of £200 a year, and their Chief Cashier the same? The Chief Rental Clerk gets no less than £170 year; the best-paid receiver of rentals in the office earns £140 a year. Not one of the collectors succeeds in touching £300 a year. What a striking example is this of Manchester of the benefits accruing from the Corporation management of gas undertakings! The Manchester Corporation have had their own gas-works longer than any other English local authority; and to-day the gas is dear and bad, niggardliness rules the administration, while scores of thousands of pounds have been squeezed out of the profits of the undertaking to be squandered in public improvements that nobody wants. To study the Manchester Corporation through all their capacities, from gas makers to hotel builders, is to receive a startling lesson in the practices of Reformed Bumbledom.

MR. L. T. WRIGHT'S LECTURES ON GAS MANUFACTURE.

The four lectures on the "Manufacture of Coal Gas," just delivered by Mr. Lewis T. Wright, at the City and Guilds of London Institute, will be found reported in the last and present issues of the JOURNAL. It is impossible, when taking

note of these aids to the study of gas manufacture, for which learners of the art are so much indebted to Mr. Wright, to refrain from an expression of regret that the accomplished author is going to voluntarily put himself out of the way of such work for some time to come. The course of lectures now under notice constitutes a complement to those delivered under the same auspices by Mr. Wright last year; and both courses follow the same lines. The first topic to which Mr. Wright directed the attention of his audience was coal; and he treated this branch of the subject in a style at once interesting and instructive. The lecturer took occasion to express his conviction that the physical formation of coal deposits is due to the agency of water currents. In dealing with carbonization, Mr. Wright stated as a novel observation that in practical working, when retorts are charged at different periods, so as to mix in the hydraulic main the yields of gas at various times after charging, the illuminating power of the whole product is higher than it would be if the retorts were all charged at the same time. In his second lecture, Mr. Wright said a good word for the carbon deposit found in clay retorts, which he does not believe represents so much loss of valuable hydrocarbons to the gas maker as is commonly supposed; and he also brought out prominently the importance of temperature in connection with washing ammonia out of gas. The third lecture was principally devoted to the subject of purification, which was dealt with in a more lucid manner than is to be met with in the ordinary text-books. Throughout his course, Mr. Wright kept in view the desirability of expounding principles and giving reasons; and he accordingly succeeded in making his teaching truly elementary in the highest meaning of the word. If his hearers were not carried beyond the contemplation of processes into an understanding of the underlying reasons, it was not the lecturer's fault. Mr. Wright has provided an admirable pattern for other lecturers who may come after him; and those students who have attended his course must be dull indeed if they do not show, in their examination-papers, the benefit of the superior advantages they have enjoyed as compared with others not so well situated.

COKE SALES.

Those who are interested in the question of coke sales will do well to read with particular attention the remarks on this subject made by Mr. H. M'L. Backler at the recent general meeting of the European Gas Company, reported in our last issue. Mr. Backler had evidently read and reflected upon the references to this matter which have lately appeared in the JOURNAL; and his statement may be regarded as his contribution towards the elucidation of the mystery of the present scarcity of coke, based upon a lengthened experience of coke-selling in many countries. It is worthy of notice that what is true with respect to the state of the English coke market is true of all the markets supplied by the European Gas Company. At all the Company's stations, there has been a good demand for this residual, so that the stocks were almost exhausted at the date when the accounts for the working year were made up. Mr. Backler stated that "within his long experience of the Company, it has several times occurred that stocks had been exhausted in this way; and when such had been the case, and the time of trial had passed away, he had observed in several instances that the increased price had been maintained, sometimes for several years." The reason given was that the "circumstances which enabled them to raise the price of coke operated some time after the trying season has passed away—that was to say, people grew accustomed to the use of coke as fuel, and they continued to use it when the price was no longer a temptation compared with other fuel." Upon further inquiry at various English gas-works where considerable quantities of coke are produced, we learn also that most of the increased demand which has kept down the stocks comes from consumers who send for it by their own carts—that is to say, it is wanted for steam-raising and other industrial purposes. This is said to be specially true in London; whence the satisfactory inference is drawn that the movement for supplanting coal by coke is gaining ground. How much of the increased demand for coke for factory uses is due to a better appreciation of its fuel value, and whether it is traceable in any noteworthy degree to the progress of the smoke abatement movement, cannot be known. It is quite possible that an increased activity of the authorities charged with the execution of the Smoke Prevention Acts may have something to do with the result; but the fact remains, and it can only be hoped that Mr. Backler's views as to permanence of an expanded demand for coke may prove well founded.

Water and Sanitary Affairs.

THE action brought against Mr. T. Hawksley, a report of which appears elsewhere, illustrates once again the difficulty of two persons looking at the same matter from a similar point of view. Mr. Burstal, the plaintiff evidently believed that it was intended he should share Mr. Hawksley's commission for superintending the construction of the new water-filtration works at Oxford. Mr. Hawksley, on the other hand, was even more strongly persuaded that nothing had been said or done to justify such a claim against him. His Counsel hinted, and with good ground, that Mr. Hawksley's position was such that a few hundred pounds would not matter to him one way or the other. He fought the case on principle; and for aught we know, although the verdict has been given against him, steps may even yet be taken to obtain the opinion of another tribunal. Certainly there was a good deal to be said on both sides. The minutes of the Oxford Corporation told somewhat in the plaintiff's favour; and the claim was further supported by the testimony of various gentlemen connected with that local body. But, when all was said, it still remained necessary to deduce the facts from conflicting evidence. The bargain which the plaintiff set up was based upon a constructive rather than a direct agreement. The arrangement on which Mr. Burstal acted, and which his friends in the Corporation seemed to have sanctioned, is not of a usual character. Mr. Charles Hawksley, who was called as a witness for the defence, and who has been his father's partner for the last twenty years, stated that the alleged agreement was distinctly contrary to professional usage in such matters; and, apparently, this statement was accepted as correct by the plaintiff's advisers. At all events it was not challenged in cross-examination. Speaking generally, it will be allowed that the functions of resident engineers and consulting engineers are by no means the same. Each should be paid for his services, but not necessarily in the same way. If the resident engineer receives a salary for the work he performs all the year round, there can, in our judgment, be no need that he should be paid, and no propriety in his receiving, a commission, which is the accepted method of remunerating a specialist, whose services are only required for the purposes of some particular undertaking. Originally the Oxford Corporation nominated Mr. Hawksley and Mr. Burstal to act as Joint Engineers for the works in question. To this Mr. Hawksley pointedly objected; and the minutes were modified. The truth seems to be that there was a prevailing desire on the part of the Corporation that Mr. Burstal should, in one way or another, obtain a share of the commission. Mr. Burstal believed that he should get it; but Mr. Hawksley denies that he assented to any such arrangement. Yet, strangely enough, though it is shown that he objected to be treated as a Joint Engineer, the jury have found that the defendant must, in reality, have contemplated acting on this footing; for how otherwise could it be held that he had agreed to divide the commission? The whole matter is unfortunate and disagreeable. But the trial may serve a good purpose in rendering people more cautious and precise when similar questions arise for consideration and adjustment.

MR. GEORGE LIVESEY AND THE GAS INSTITUTE.—We have received the following from Mr. G. Livesey, and are asked by the writer to state that, as it is the sequel to the communication which appeared in the JOURNAL for July 12 last year, he is desirous that it should receive similar publication:—

[COPY.]

5, Camden Park, Tunbridge Wells, July 24, 1888.

W. H. Bennett, Esq., Secretary, The Gas Institute.

DEAR SIR,—My letter of Friday last, the 20th inst., informed you that the time for carrying out my determination to resign if Mr. Bray remained a member, had arrived. The formal notice was delayed for a reason that no longer exists. I therefore now resign my seat on the Council, and withdraw from membership of The Gas Institute; and have to request that you will make the necessary arrangements for relieving me of the position of Trustee.

It is with great regret that I sever myself from the Institute after a very pleasant connection of nearly a quarter of a century, during which I have made the acquaintance, and I hope I may say the friendship, of so many worthy men engaged in the gas industry. But Mr. Bray's conduct has been, and continues, of such a character that I can take no other course than that indicated immediately after the meeting at Glasgow, from which I have never wavered—that with Mr. Bray as a member I cannot remain in his company in the Institute.

I can never forget the many acts of kindness, and the honours done to me by the members; and I trust that, notwithstanding this official severance, the old kindly feeling may long continue.

Yours faithfully,

GEORGE LIVESEY.

Essays, Commentaries, and Reviews.

GAS AND WATER COMPANIES IN THE STOCK MARKET.

(FOR STOCK AND SHARE LIST, see p. 218.)

THE course of business on the Stock Exchange during the past week has been rather unsteady. The tendency at first was all upwards; the general outlook, political and otherwise, being in favour of peace and prosperity. A slight reaction set in about the middle of the week; some of the markets lacking support. The tendency, however, was again favourable at the close. With the advent of August, business will probably become much more restricted; and the markets will show less animation. Money is easier. In the Gas Department, business has been quite up to average. The feature of the week has been the relapse of Gaslight "A," which, after touching 263 the week before, fell away till, on Friday, it marked 256½. This is really a low price; and we think an immediate improvement may be looked for. At the present quotation, the stock may be purchased to pay a clear 5 per cent., with a dividend of £6 10s. payable in a month. All other variations in price are upward. Gaslight 4 per cent. debentures are higher. A large parcel of this stock was sold at the Mart on Wednesday at about 119½; but on Saturday it was done in the market at 121. South Metropolitan have been quiet, at good firm prices. There has been more demand for Commercial; and the old stock marks another slight advance. Of the Foreign Companies, Imperial Continental has been fairly active and very steady. Some of the minor undertakings have improved. The second mortgage of Chicago has advanced 3; and Monte Video and San Paulo are each ½ better. Among the Water Companies, Lambeth has been the most active; but in none has business been more than moderate. Several, however, continue to make the small movements upward which we noted last week. New River pays the now invariable dividend of £6 1s. 3d. for the half year. The daily operations were: Good business in Gas on Monday; many issues being dealt in at steady prices throughout. Commercial old advanced 1; and Monte Video and San Paulo, ½ each. Water was quiet and unchanged. Gas was much less active on Tuesday; few issues being touched. Gaslight "A" was not done at all; and the quotation began its fall by dropping 1. Prices of all others were steady. Water was an absolute blank. Wednesday was another quiet day for gas. South Metropolitan "A" was done as high as 323; but quotations did not move. One or two Water stocks changed hands, at good prices. Thursday would have made little business in Gas, but for the set against Gaslight "A," which dropped 3. Everything else was quiet and unchanged. Water was strong; Kent advancing 2, and East London, Grand Junction, New River, and Lambeth 10 per cents., 1 each. Friday opened very heavy for Gaslight "A;" but it went no worse, and the closing mark was the best of the day. Very little else was dealt in, and business altogether was moderate. Several Water issues were done at good average figures. On Saturday, Gaslight "A" was steady at the previous day's figures. The 4 per cent. debentures rose 1. All else remained quiet and unchanged. A single transaction in Lambeth 10 per cents. comprised the business in Water; and all quotations were without variation.

ELECTRIC LIGHTING MEMORANDA.

PROSPECTIVE REVIVAL OF ELECTRICAL SPECULATION—EFFECTS OF THE RECENT JUDGMENT IN THE EDISON PATENT CASE—ELECTRIC LIGHTING OF THE ADELPHI THEATRE—THE POWER OF ELECTRICITY TO PRODUCE A VACUUM.

THE revival of projects for electric lighting ventures, in consequence of the recent alterations of the law, to which we have drawn attention in this column for several weeks past, has attracted the notice of the financial press; and it is to be gathered that an attempt will be made to repeat the speculative developments of six or seven years ago. Prophecies are being freely uttered that, in consequence of the great development which electrical science has made during the past few years, new electric lighting companies may now, with good management, do a very profitable business in any of our large towns. Great stress is laid upon the assertion that many of the electric lighting companies of the United States are paying large dividends. A New York Company, "operating under difficulties at least as great as would have to be encountered in London, earns easily 12 per cent. on its capital. The City of Cincinnati shows an annual profit of 20 per cent.; while some second or third rate towns in the State of Pennsylvania pay from 12 to 22 per cent." This is precisely the kind of vague flourish with which the speculator waves his bait before the eyes of the man who, with a little money lying idle at his bankers, is constantly on the look-out for a profitable investment. The difference between the cost of gas in the United States and in England is either ignored or belittled as a consideration of no real moment. The *Financial News* recently published an article of this kind, with the object of advertising the South Metropolitan Electric Lighting Company, who, as we have already announced, are endeavouring to obtain a Provisional Order to enable them to commence business in a West-end district. It is reported that this concern has two schemes in hand at present—one for a lighting station at Whitehall, which is to be ready by October, and the other for an installation in Lincoln's Inn Fields. Some good names are associated in this enterprise, and much interest will be felt in its fortunes. Newspaper writers may prophesy as they will; but while we do not deny that a fair amount of business in lighting *de luxe* may await the first well-

managed West-end Electric Lighting Company that can reap it, it is very certain that gas at London prices will be a hard nut for the most skilful electricians to crack.

The electrical journals continue to occupy themselves with discussions as to the effects of the recent decision of Mr. Justice Kay with reference to the Edison and Chesebrough patents. It is concluded that the maintenance of the latter patent for "flashing" carbon filaments in an atmosphere of hydrocarbon vapour will practically keep the monopoly of low-priced and reliable lamps in the hands of the Edison and Swan Company, because, although good lamps can be made without flashing, it is such a very convenient process, that it has considerable economical recommendations. Meanwhile, now that attention has been concentrated upon the Chesebrough patent, rumours are circulated to the effect that it was anticipated by somebody else. It can be very well understood that one result of such a judgment as that of Mr. Justice Kay in the case under notice would be the careful overhauling of all records bearing, however remotely, upon the question at issue; and there is no knowing what may turn up to reward careful search. It used to be said that Truth hid herself in a well; and this was regarded as a strong metaphor illustrative of the difficulty of getting at her. The old-fashioned dug-out well was meant when the metaphor was originally hit upon, when also patent litigation was unknown. It is fortunate, for the sake of the metaphor, that, thanks to the diamond drill, the depth of wells now-a-days keeps pace with the profundity of the search for Truth in connection with a patent case in the Chancery Division.

The Adelphi theatre in London is one of the latest examples of isolated electric lighting; the work having been just finished by the Edison-Swan Company. It is a rather large job—comprising about 1500 lights in all; and there is some novelty in lighting the auditorium by means of eight incandescent lamps, each of 200 candle power, suspended from the middle of the dome. Shadows are obviated by ornamental bracket lights in front of the tiers of boxes; and there are single lamps where required. Elaborate provision has been made for the production of scenic effects. The engine-room is in the basement of a house in a court adjacent to the theatre; the plant consisting of three 156-horse power Babcock and Wilcox water-tube boilers, working at a pressure of 140 lbs., and four Willans compound high-speed engines—two of 75, and two of 180 horse power, coupled direct to four Edison-Hopkinson dynamos. It will be observed that this is a large plant for the lighting of one theatre; but it appears to be intended to extend the lighting to an adjoining restaurant, and to as many other buildings in the neighbourhood as can be supplied. Of course, the installation has been worked out in the most superior manner; and the proprietors contemplate being able, "in the course of a few weeks, to entirely dispense with the gas service throughout the theatre, as far as lighting is concerned." Wherefore we shall not be surprised at any time to hear that the new light has gone out at an awkward moment. Like the other electrically lighted theatres of London, the Adelphi will probably continue on the books of the Gas Company.

For a long time past the announcement has been made that an experiment would be set on foot with the object of practically solving the question whether the trains on the Metropolitan Railway—called by London cabmen "the sewer"—can be drawn by electric motors instead of steam locomotives. It has now been explained that the delay in fulfilling this promise has arisen from the necessity of providing a substitute for the vacuum brake fitted to all trains on this railway, and without which, or something equally reliable, the Board of Trade will not permit the line to be worked. Lord Bury, the Chairman of the Electrical Company which is supposed to have the business in hand, has written to the Directors of the Railway Company, with a view to publication, a letter in which he says his people have been in treaty with the Vacuum Brake Company to devise some way of working these brakes without steam. Upon this announcement the *Electrical Review* is unkind enough to remark that the vacuum which the electrical locomotive in question will make will be in the coffers of its creators. Unfortunately, electrical companies have displayed only too great facility in the production of this kind of vacuum.

THE COMPULSORY ELECTRIC LIGHTING OF THEATRES IN MADRID.—The Madrid Correspondent of *Industries* states that, in connection with the compulsory electric lighting of theatres, the Government have declined to grant any extension of time. No theatre will be allowed to re-open in the forthcoming autumn unless the order has been complied with. Most of the theatres have already made arrangements for their installations.

THE SALFORD CORPORATION AND THE GAS INSTITUTE.—The following resolution, notice of which has been given by Mr. Mandley, is set down for consideration at the meeting of the Salford Town Council to-morrow:—"That, in view of the positive and apparently incontrovertible assertion made by Mr. George Bray, C.E., in his pamphlet entitled 'Corrupt Practices in the Gas Industry,' namely, 'that corruption in the gas industry has been largely fostered by the policy pursued by the Council of The Gas Institute,' no further subscription be paid, nor any other support whatever be afforded by or on behalf of this Corporation, to The Gas Institute; and that it be a standing instruction to the Gas Committee that they shall, whenever occasion arises, express their strong disapproval of membership of the said Institute being entered into or maintained by any of their officials."

A GASHOLDER WITH PARTIAL GUIDE-FRAMING.

ON Wednesday last a highly interesting and important experiment in structural gas engineering was successfully carried out at the Rotherhithe Station of the South Metropolitan Gas Company, when in the presence of Mr. George Livesey, Chairman of the Company, Mr. Frank Livesey, Chief Engineer, and Messrs. John Somerville and A. F. Browne, of the Company's engineering staff, a three-lift gasholder, of which the guide framing only extended to the height of the second or intermediate lift, was for the first time inflated to its full height. The problem discussed on various occasions by Mr. G. Livesey, Mr. V. Wyatt, Mr. W. H. Y. Webber, and in the valuable series of "Communicated Articles" upon the stability of gasholders which appeared in the last two volumes of the JOURNAL, has therefore received its first practical solution; and from henceforward the most conservative of gasholder builders must confess that the principles of this particular branch of gas engineering have received a fresh development. Members of The Gas Institute and others who have followed the technical transactions of that body at Glasgow last year, will remember that mention was then made, in connection with Mr. Webber's paper on "The Guide-Framing of Gasholders," of this proposed experiment at Rotherhithe. We have kept the matter in view ever since; having been determined, with Mr. Livesey's permission, to report the result of the test, whatever it might be, so that there should not be any misapprehension concerning the effect of such a grave departure from custom. It is with particular pleasure that we are now able to signalize the triumph of the new principle. The theoretical discussions of this question have had the most satisfactory of all possible sequels; and we are gratified to-day in being able to congratulate together those engineers who paved the way for, as well as those who have carried out this most striking of modern developments of gas engineering construction.

The conditions of the Rotherhithe experiment require to be explained in detail. The holder selected for the test was a not very modern double-lift one, 150 feet in diameter, with 25-foot lifts, in a wrought-iron tank only half-sunk in the ground. The site is very close to the River Thames; and the subsoil is full of water. The fact of the tank being constructed of such comparatively yielding material as wrought-iron plates standing to a height of 12 feet clear above the ground, was not favourable to the execution of the scheme, which depends for success upon the existence of a high degree of rigidity and strength in the bottom guiding arrangements. In this case the essential rigidity was absent. The 12 feet of tank plating above ground was not even supported against the guide-columns; and the top edge of the tank was finished off with an absurdly light channel-iron curb, put on apparently more to prevent the look of a "raw edge" to the plating than with any idea that strength was desirable to keep the circle true at this point. The guide-framing for the holder consists of massive cast-iron columns of the old regulation Doric pattern, with a high rectangular base, standing on heavy blocks of Bramley Fall stone. The guide-channels, which start from the top of the tank, are of H-iron, connected to the columns by the usual cast-iron chairs, originally about 5 feet apart. There were no diagonal braces; but there was one tier of lattice girders half way up, and another at the top of the columns. It was all very massive-looking—quite a typical old-fashioned substantial piece of work; very heavy, very expensive, and supposed to be very strong. It should be stated that the crown of the inner lift was very heavily framed, in a style that will be understood when it is remarked that the main tie-rods are 2½ inches in diameter. Altogether, this lift has to carry up and down with it every time it rises and falls about 80 tons of superfluous metal; and is accordingly by so much more top-heavy than it need be. This is perhaps all the better for the purpose of the experiment, because it may be said that if an old-fashioned top-heavy structure such as this can be sent up and down without guide-framing, there need be no fear of attaining similar success with more favourable specimens.

As might have been supposed, when this solid, respectable piece of work (which cost the now extinct Surrey Consumers' Gas Company a pretty penny at the time it was built, now some one-and-twenty years ago), came to be examined critically, with a view to the proposed addition of another lift, its apparent strength considerably dwindled. To begin with, it was possible for a man sitting on the grip of the outer lift, when grounded, to spring with his feet the top of the tank at any point of the circle. The bottom curb of the outer lift, upon which, according to the new theory so much depends, was anything but so strong as was desirable; and the bottom rollers, carriages, and guides were likewise inferior in strength. The work was reinforced, however, as thoroughly as circumstances permitted; no great expense being incurred for the purpose. A horizontal plate, forming a flat girder, was fixed upon the top curb of the tank, which was thus prevented from springing when the bottom rollers should come into play. There was a tank guide on each side of the position of every column, and about 5 feet from it. These guides originally stood out from the tank plates, being bolted against distance-pieces or washers. They were filled in solid with concrete between the guide and the tank plating; and, in addition, raking struts were bolted outside the tank between the line of the guides and the columns. The space between the tank plating and the columns was also filled in solid with concrete. The effect of these measures was to bind the tank and its guides to the columns in a very much more rigid manner than was previously the case. Strong flat diagonal bracings were also provided between the columns; and tangential rollers were added to the middle and lower lifts. The chairs connecting the column guides to the columns were doubled

in number by the insertion of intermediate ones. The result of these reinforcements was to improve the working of the holder even before any attempt was made to employ the additional third lift. It had originally listed as much as 5 inches in one direction; but the increased rigidity of the tank, and the consequent greater resistance of the tank guides, diminished this by two-thirds. Even thus, however, it seemed like a straining of the new theory to apply it to a holder that was known to have a permanent list of two or three inches. If it was so much out of the perpendicular *with* guide-framing, what would the inner lift be *without* this safeguard?

Notwithstanding this cause for disquietude, the preparations for dispensing with the guide-framing for the top lift of the enlarged holder were pushed on. The radial rollers and goose-necks of the top lifts were retained; but the last length of the column guides, at the level of the tops of the columns, was bent outward with a circular curve, so as to permit of the easy disengagement and re-engagement of the rollers upon ascending and descending. This is all that a curious observer can see when the holder is empty, or only partly full, to distinguish the guide-framing from that of any other gasholder; and it is nothing very extraordinary to look at. The guide-framing is simply that of an ordinary double-lift holder; and nobody who should see it from a distance when not fully inflated would suspect it of being anything different. We make a point of this, in order to show that there was nothing elaborate or noticeable in the preparations for the experiment.

Everything was ready last Wednesday morning for the crucial test of the holder's ability to work without guide-framing for the last third of its height. When the chief officials of the Company arrived on the scene, the holder was two-thirds full, and the top guide-carriages were even then clear of the guides by a space quite sufficient to prove the stability of the holder under the novel conditions, for it was *not supported in any way above the rollers on the grip of the middle lift*. To this extent the holder has been regularly worked all through the past winter; and therefore the success of the principle may be said to have been assured long ago. But, for a variety of reasons, the final test of raising the holder to its full capacity was not attempted until last week. A few minutes before half-past ten everything was ready, and the order was given to proceed. Rivet after rivet slowly rose out of the tank, when a discharge of water from the cups indicated that the holder was taking fresh bearings, and the exhaustor was temporarily stopped while the various water-levels were verified. The engine was then re-started; and the holder rose uninterruptedly, with a steady gauge, until 12.30, when it was reported full. It then presented a remarkable spectacle—the top carriages and rollers stretching out in the air far above the guide-columns; but the height above the ground took off the awkward look, that might be supposed in the circumstances, of the holder "stretching out its arms helplessly in the air, as though seeking for support and finding none." Indeed, the spectators of the curious sight remarked that it looked less odd than might naturally have been expected. When full, the holder showed itself to be about 2½ inches out of the level, which was less than was usual with the double-lift before it was improved in the manner stated. Latterly, however, the two lifts have worked with a list of only 1 to 1½ inches; so that the abandonment of the guide-framing for the top lift apparently increased the list by rather more than an inch. It was found on examination, however, that the rollers on the intermediate and lower lifts required adjustment; and this is to be attended to forthwith, when it is expected that the apparent excess of list will be corrected. Owing to the weakness of the bottom curb of the holder, already noticed, and to a slight defect in the plumbing of the columns that cannot now be conveniently corrected, the holder may always remain a little out of the perpendicular. We learn that since Wednesday the holder has been filled and emptied regularly; all three lifts working with the utmost steadiness. Inspection of the bottom rollers, rendered possible by the full raising of the holder, has revealed that they do not fit properly. They are found to bear tight on the higher, and not to touch the guides on the lower side. When this is put right, it is expected that the holder will work level, or pretty nearly so.

We have now described the nature and course of last Wednesday's experiment in every particular. It only remains to state that the day was stormy—the wind sweeping over the works in sharp, but irregular gusts. The wind's direction and force were, however, immaterial, as they had no effect at all upon the holder, which did not show the slightest tremor during the heaviest squalls. At the conclusion of the test, Mr. G. Livesey expressed himself as perfectly satisfied with the result, which practically marks a new era in gasholder construction. Henceforward there will be no reason whatever for carrying guide-framing to the full height of a three-lift gasholder, to say nothing of a four-lift one; and the extent to which the framing may be safely cut down must be matter for further experiment on the first convenient occasion, since it would be wrong to assume that the Rotherhithe test exhausts the possibilities of advancement in this direction. It should be remarked that this experiment has been made at very little cost, for all the measures we have described, which had for their object the cure of weaknesses of the old structure, would have been equally necessary, even if a third tier of guide-framing had been contemplated. No prudent engineer would think of adding another lift to a telescopic holder considerably out of level without endeavouring to remedy the old defect; and that is what has been done in the present instance. The whole course of the treatment of this Rotherhithe holder is a lesson in the principles

of gasholder stability, and conveys much information to gasholder builders. It shows that monumental structures are not necessarily strong, and that massive Doric columns and heavy crown trussing are not enough by themselves to constitute a trustworthy holder. Regard for right principles is the only fountain of security in gasholder construction; and the most important principle of the art may be briefly, if somewhat imperfectly, summarized in the aphorism, "Take care of the bottom, and the top will take care of itself."

It should be stated that the cost of the double-lift holder and the wrought-iron annular tank was £25,000 in 1867, or (as the content is 825,000 cubic feet) about £30 per thousand cubic feet. The expense of adding the third lift was £2550; and the strengthening of the tank cost less than £200.

THE GLASGOW INTERNATIONAL EXHIBITION.

SEVENTH ARTICLE.

THE Glasgow Exhibition provides us with two instances of the practical manufacture of illuminating gas, in both of which the raw material forming the source of the gas is mineral oil—semi-refined petroleum, or that product which is known as the "intermediate" oil of the Scotch shale-oil works. Both systems claim to be specially suitable for adoption at country mansions, large factories of various kinds in villages, and other places that have not yet been brought within the civilizing influence of an ordinary gas supply, and for large hotels, halls, railway stations, &c. These small gas-works are both "outside exhibits," and closely adjoin each other immediately outside the North front of the Machinery Court; and on the occasion of the visit of the North British Association of Gas Managers to the Exhibition last Thursday, they received the attention of skilled experts in gas-making operations.

First in order, may be mentioned the exhibit of the Paraffin Gas Lighting Company, Limited, of Glasgow, whose process (the patent of Messrs. Alexander and Paterson) was shown at the Edinburgh Exhibition two years ago, and which has since been adopted in the Fifeshire village of Colinsburgh. It may be remembered that, in connection with this Colinsburgh installation, there have been two or three lively and interesting passages of arms, in which Mr. Macpherson, the well-known Gas Manager at the "Lang toon o' Kirkcaldy," has taken a prominent part. It seems reasonable to suppose that the intermediate oil used by the Company as the source of the gas should give a product which is quite free from sulphurous and ammoniacal impurities; and that the gas shown at the Company's stand has a very high illuminating value goes without saying. Assuming that it is of 60 or 65 candle power, questions such as these arise: Can anything like this illumination be got out of it in actual practice? Can it be adopted, as an economical alternative, in lieu of ordinary coal gas? It is well known that the suggestion to test the process on a large scale has been several times before the Glasgow Corporation Gas Committee; but up to the present the negotiations that have been carried on have not been attended with any practical result, partly, we believe, in consequence of no tangible or feasible proposal having been made to them by the Paraffin Gas Lighting Company. The Company seems to be making some progress, though not in Glasgow itself. Last year sixteen works were erected by the Company, who are at present in negotiation with Steveston, in Ayrshire, and Oban, in the Western Highlands, for the erection of works, even though ordinary gas-works exist in both places. Notwithstanding the very strong statements made regarding the oil gas manufactured at the Colinsburgh Gas-Works, the Secretary of the Company, so recently as the end of January of this year, reported favourably of the gas which they have been supplying to their customers. Their now Manager keeps accurate statistics daily of the quantity of oil used, the time occupied in making the gas, the total make, and the yield of gas per gallon of oil. He can therefore speak with perfect confidence as to the working of the system. Taking the two months ending Dec. 31, 1887, he gives the following figures:—

	Cubic Feet.
Total make of gas	97,666
Total gas consumed, as per meter	81,800
	15,866
Deduct street lamps, which burn free, say	1,000
Unaccounted-for gas	14,866

Or 15½ per cent. of the total make. The Secretary of the Gas Company goes on to state that the quantity of oil used was 1057 gallons, and that the amount of gas yielded (97,666 cubic feet) was equal to 92½ feet per gallon; while the maximum quantity registered to the gallon was 97.18 cubic feet, and the minimum 76.1 cubic feet. In order that customers may be able to compare the price of the gas with that of coal gas, they are charged by the Company every 1000 feet as 2500 feet. As the gas is of 65-candle power, this equalizes it with coal gas of 20 candles—at least so says the Secretary. When the paraffin gas was introduced into the village of Colinsburgh, the price of the coal gas was 7s. 11d. per 1000 cubic feet. But the price of the gas now used has been reduced to 6s. 3d.; and the Secretary says that after feeling their way, he is certain they will be able to reduce the price very much further. He reports that the light gives the greatest satisfaction, as it is very brilliant and perfectly free from smoke and sulphur. His next statement must be taken with a certain amount of reserve. It is that the atmosphere of rooms is not in the slightest degree vitiated by the gas; the heat which it generates being, in his opinion, a healthy one. We would in passing ask him, "What becomes of the large amount of carbonic acid which

is produced by burning gas which is so exceedingly rich in carbon?" On the question of the economy of the gas, where it is made for general consumption, he comes to a very practical conclusion—that the system may with confidence be adopted in towns where the price of coal gas is more than 3s. 6d. per 1000 cubic feet.

The other exhibit of oil-gas plant referred to is that of Messrs. E. Mansfield and Sons, of Manchester. Their apparatus is designed for the economic manufacture of gas from cheap oils and fats; the gas produced being suitable for illuminating purposes and for motive power. The process of manufacture is shown at the stand ("intermediate" shale oil being used); the storing of the gas in a somewhat capacious gasholder; and subsequently the use thereof as the motive power for driving a Crossley "Otto" gas-engine, which is installed within a little glass house, attracting the notice of many visitors. Within the same house, after nightfall, the gas is shown in use as an illuminating agent. The apparatus used in this instance, as in the other, is exceedingly simple; indeed, the simplicity of the whole arrangements is quite remarkable, and the operations can all be conducted by an unskilled person. The gas produced by the apparatus bids fair to aid materially in extending the use of gas engines both at home and abroad.

THE ARTESIAN BORING IN THE CITY.—The contractor for the artesian well which the Commissioners of Sewers are sinking at Aldgate have now been at work for twelve months, and have only gone down about 130 feet out of the 350 feet which they have to bore. This portion of the well has been an expensive piece of work; but the Engineer (Mr. W. Haywood, M. Inst. C.E.) considers that it is not the most difficult.

PRACTICAL HINTS ON GAS CONSUMPTION.—In a little brochure, bearing this title, Mr. Joseph Shaw, of Lockwood, Huddersfield, shows the advantages to be derived from a proper application and use of gas, and how to obtain the best results therefrom. The author being the inventor of a gas-governor, it is only natural to suppose that in the portions of the little book which point out the remedy for excessive gas bills, the merits of this appliance should be enlarged upon. However, any information which enables gas consumers to burn their gas more rationally than they now do in too many cases, should be welcome, as tending to remove dissatisfaction. A useful accompaniment to the book is Mr. Shaw's meter-card, which, by means of printed dials furnished with moveable pointers, instructs consumers how to read their meter indices.

DEATH OF MR. J. O. N. RUTTER.—We regret to have to announce the death last Friday, at Black Rock, Brighton, in his 90th year, of Mr. John Obadiah Newell Rutter, F.R.A.S. Mr. Rutter's name has been for many years associated with the gas supply of Brighton; he having filled the position of Engineer of the Black Rock works. On the amalgamation of the Brighton Gas Companies about six years ago, he was offered a retiring pension. But he preferred to continue to discharge his accustomed duties; and this he did almost to the last. Mr. Rutter always displayed great interest in questions connected with gas engineering; and was a frequent contributor to the earlier volumes of the JOURNAL. His last communication—on the subject of "Gas Lighting and Ventilation"—appeared about three years ago. He was the author of several pamphlets; that on the "Advantages of Gas," which reached its 204th thousand, being the most conspicuous. Interested as he was in matters appertaining to his profession, Mr. Rutter never attended any of the meetings of The Gas Institute, of which he was an honorary member. He nevertheless testified his appreciation of one branch of the Institute's work by presenting the Committee of the Benevolent Fund with a donation of 100 guineas—a munificent gift which was announced in the report presented at the meeting of the Institute held at Sheffield in 1883. Mr. Rutter has passed away after a long life of useful work; and his departure severs one more link connecting the present with the past of gas engineering.

NORTH OF IRELAND GAS MANAGERS' ASSOCIATION.—The annual meeting of this Association, the formation of which, as the result of a movement initiated by Mr. J. Whimster, of Armagh, was announced in the JOURNAL in September last year, is fixed to take place at Lisburn on the 14th prox., under the presidency of Mr. E. Stears, Engineer and Manager of the gas-works in that town. The Honorary Secretary of the Association (Mr. J. Whimster) has issued a good programme of business; as, in addition to the President's address, three papers on subjects immediately connected with gas-manufacturing operations, and one on gas companies' policy, are set down for consideration. The last-named matter will be introduced by Mr. T. Travers, of Cork, who will give the members his views in regard to the best way of assisting consumers. Mr. J. Robb, of Limavady, will describe a retort-setting for small gas-works; Mr. A. Waddell, of Newtownards, will relate his experience with Mr. G. R. Hislop's regenerative furnace; and Mr. W. B. Featherstone, of Dundalk, will deal with the utilization of tar. At the close of the proceedings, the members will dine together in the Railway Hotel. The first business meeting of the new Association promises to be very instructive; and it is to be hoped the Committee and Secretary will receive the co-operation of all Irish gas managers to increase the usefulness of the society. It is frequently inconvenient for Irish gas managers to cross the Channel to attend the meetings of their English and Scotch colleagues; and, in view of this fact, there is the greater need of some such means of intercommunication as that afforded by this Association.

Notes.

PROOF OF THE HOLLOWNESS OF A BUNSEN FLAME.

It is generally known that the flame from an ordinary Bunsen gas-burner is a hollow cone, the interior of which is filled with air. This fact is proved by the classical experiment with a match thrust into such a flame, when the parts in contact with the edges of the flame ignite while the interior remains intact. *La Nature* gives another very simple method by which the figure of the

longitudinal section of a Bunsen flame may be obtained through the instrumentality of the flame itself. All that is necessary is to take a piece of metallic tube of sufficient size, as shown in the figure, and wrap round its outer surface a piece of filter-paper, which is kept in position by the fingers. This paper is then to be presented to a Bunsen burner in the manner indicated, and in this way, after a trial or two, the form of the section of the flame as shown will be obtained. As the portions of paper which touch the flame carbonize more quickly than the rest, it is advisable to put underneath the sheet of paper (above the dotted line of the drawing) a second piece, which serves to diminish the conductivity of the metal at this point, and gives more uniform results. This demonstration is calculated to be specially useful as a class experiment.

FLOORING FOR ENGINE-HOUSES.

Much difference of opinion prevails as to the best flooring for engine-houses and machinery-rooms. Tiles are greatly favoured, but have the drawback of rigidity, and do not lend themselves to occasional necessary disturbances and rearrangements of the floor area. The *Deutsche Bangewerkes-Blatt* recommends long narrow oak panels for the floors of engine-houses. The wood should be perfectly dry, being stored for some time, if necessary, in drying-stoves. It might be suggested that retort-houses in gas-works would form admirable drying-places for hard woods. The oak panelling should be laid upon oak joists, and nailed down with 4-inch wire nails at close intervals. It does not much matter whether the oak flooring is laid in compartments or in long planks with alternating butt-joints. In the latter case, however, the planks must not exceed 2½ inches in width. A floor laid in this way has all the advantages of cleanliness and durability attaching to the best parquetry. It will not warp, notwithstanding the vibration and other disturbing influences to which it is liable to be exposed in an engine-house. The cost will vary according to circumstances; but it would not, in most cases, be so great as that of a good tiled floor.

A WATER-LEVEL INDICATOR.

A convenient device for indicating the water-level in wells, bore-holes, &c., is described in the *Journal de l'Eclairage du Gaz*. It is recommended as a very simple process; and is employed by the Engineers of the service of the Ponts et Chaussées for their new tide indicators. It consists in covering a small copper tube, which is the sounding instrument, with a sheet of paper impregnated with a solution of sulphate of iron, rubbing it over when dry with a pad dipped in powdered gall-nut. The paper thus prepared takes, when plunged into water, a very pronounced black tint, in consequence of the reaction of the iron salt upon the tannin, forming ink. It is remarked that this process is susceptible of many modifications, and may find several applications in connection with gas apparatus. It is suggested, for example, that it could be used to record maximum pressures in water gauges, and in other hydraulic appliances employed in gas-works. In the case of pressure gauges, to convert an ordinary gauge into a recorder of maxima it would suffice to insert a strip of sensitized paper into the branch communicating with the air. If, in consequence of the capillarity of the paper, the water-line indications became a little confused at the end of a prolonged immersion, strips of parchment or parchmentized paper treated the same way could be used instead of plain paper.

THE COMPOSITION OF THE ATMOSPHERE OF WORKSHOPS.

The extent to which the atmosphere is altered in composition in workshops and factories of different kinds is a matter of great importance in connection with scientific ventilation. Dr. Schuler, a Swiss inspector of factories, has recently published some useful information upon this point. He visited 180 industrial establishments of various kinds, and made carbonic acid determinations in

the workshops. The result was as follows:—In a finishing-shed the proportion of carbonic acid was as low as 0·40 per cent. In four carding-sheds there was 0·68 per cent.; in 27 cotton-spinning mills there was 0·69 per cent.; in five twist-sheds there was 0·79 per cent.; in six foundries and machine-shops, 1·24 per cent.; in nine printing-works, 1·73 per cent.; and in sixteen silk-mills, 2·21 per cent. To diminish the proportion of carbonic acid in workshops, Dr. Schuler proposes, in default of special means of ventilation, to put a perforated plate in every window. The difference between the exterior and internal temperatures would produce an energetic draught. Experiments have shown that the rate of passage of air through the perforations of a plate will range from 633 mm. per second with a difference of temperature of 17° C., to 725 mm. with a difference of 24° C. M. Delahaye, who notices this subject in the *Revue Industrielle*, remarks that Dr. Schuler recommends perforated metallic plates for this makeshift ventilation; but the perforated glass of M. Appert, in which the holes are conical, would be preferable, as their use would not entail any sacrifice of light.

SOCIETY OF ENGINEERS.—Last Tuesday, the members of the Society of Engineers accompanied by a number of gentlemen interested in sewage disposal, visited the new precipitation works at the Barking outfall sewer, now erecting, under the authority of the Metropolitan Board of Works, for the deodorization of the sewage falling into the Thames from the northern parts of London. Among those present were: Mr. A. T. Walmisley (President); Messrs. J. R. Baillie and H. Adams (Vice-Presidents); Messrs. Jabez Church and Charles Gandon (Past-Presidents); Messrs. C. Anderson and J. H. Cunningham (Members of Council); and Mr. G. A. Pryce Cuxson (Secretary). The party went by steamboat; and on their arrival at Barking landed at a temporary pier, near to where the whole of the North London sewage is conveyed to Barking by three great sewers—the high one from Islington, the middle one from the north side of Hyde Park, and the low one from Chelsea; the contents of the latter being pumped to high chambers, whence it is delivered into the Thames on the turn of the tide at high water. The visitors were received by Mr. G. Marshall, on behalf of Sir J. W. Bazalgette, C.B., the Engineer of the Board, who fully explained the works, which extend over an area of 50 acres.

ARTESIAN WELL BORING AT GAINSBOROUGH.—The Gainsborough Local Board have for nearly four years been engaged in an attempt to improve the water supply of the town, and, if possible, to abandon the use of the water from the Trent, which is often very unsatisfactory. In 1884 the Board determined to bore for a supply of water, and agreed to spend £2000 in the experiment. During last year, after considerable discussion, it was decided to spend a second sum of equal amount to the first. When this had been done, a test of the quantity and quality of the yield was made, with the result that only about one-fourth the quantity required for the town's supply was obtained; and as to the quality, the five analysts to whom the water was sent varied considerably in their opinions as to its purity, but they were all of opinion that it was very hard. Another attempt has been made recently to increase the yield by piercing the Bunter sandstone 100 feet further; and this was concluded on the 20th inst. The depth of the bore is now 1200 feet below the surface; the diameter of the bore-hole in the sandstone being 12 inches. The Local Board have agreed to first test the yield by pumping continuously for 16 days and nights, and then ascertain, by means of a 1000-gallon tank, the exact number of gallons per hour obtained. The result of the testing is looked forward to very anxiously by the inhabitants, as the cost has already exceeded £5000.

SMOKELESS FUEL.—The following letter appeared, under the initials "T. N.," in the *Manchester Examiner* last Tuesday:—"The waste of smoky chimneys has often been pointed out; but no practical effort has been made to avoid it. The manufacturing world and private individuals seemed to be awed by the magnitude of the task. Feeble efforts have been made to 'cure the smoke nuisance' by using some contrivance or other for consuming the smoke after it has been made; and the aspect of Manchester and Sheffield show with what little success. The best way to render our towns free from smoke is to make no smoke. Some persons may think this an impossibility; but if the following figures are correct, it is not only possible but highly probable. The figures are professed to be the result of trials made in the last few weeks at a bleach works near Nottingham, and are said to be verified by representatives of the owners of the works, as well as by those of the London Mercantile Gas Company, Limited, who supplied the gas and coke producers. Here they are—

	Coal Firing.	Smokeless Fuel.
Coal used in gas and coke producers and in the boiler to raise steam to 81 lbs.	628 lbs.	504 lbs.
Do. the next hour	785 "	224 "
Do. average per hour while working	471 "	224 "
Water evaporated, do.	3480 "	3543 "
Do. per pound of coal	7½ "	15½ "

The smokeless fuel is simply small coal turned into gas and coke. The gas and coke are then burnt in the boilers instead of coal; and, according to these figures, give more than double the heat. We wish every success to those who can produce such results. Absence of smoke, and duplication of the power of fuel, will prolong our lives and our coal-fields at the same time."

Technical Record.

NORTH BRITISH ASSOCIATION OF GAS MANAGERS.

ANNUAL MEETING IN GLASGOW.

The Twenty-seventh Annual Meeting of the North British Association of Gas Managers was held in Glasgow (in the rooms of the Philosophical Society) last Thursday, with Mr. David Terrace, of the Glasgow Corporation Gas-Works, Dawsholm, as the President. There was an unusually large attendance.

After the meeting was constituted, Mr. Robert S. Carlow, the Secretary, submitted the annual report of the Committee of Management. It gave a comprehensive *résumé* of the business done during the past year. The remit on "The Best Standard Burner for Scotch Gas" had been under the consideration of the Committee; and it had been resolved to place the results of the testing of the burners in the hands of Mr. Geo. R. Hislop, the Convener of the Sub-Committee on the question; and he had undertaken to prepare a paper upon the subject for the meeting. The report stated that the Research Fund had now been contributed to by fifty gas companies. It also referred to the endeavours resolved upon a year ago to institute an investigation into the purification of coal gas in closed vessels. Arrangements could not be completed in time to admit of a report being presented to the meeting; and it was recommended that the Special Sub-Committee which had been appointed, should be requested to continue in office for another year. During the year the Benevolent Fund had been drawn upon to the extent of about £20. After dealing with some other matters, the report stated that it had again been considered advisable to postpone taking definite action in reference to the Murdoch Memorial. There had been subscribed to the Memorial Fund the sum of £287; and the Committee intended to make further efforts to increase this amount. Mr. Robb, of Haddington, had made an offer to the Association to present to it his bound volumes of the JOURNAL, &c., on the condition that a "home" be provided for them in Glasgow or Edinburgh. The Committee of the Association, owing to this condition, had very unwillingly been compelled to decline the proposed addition to the property of the Association. There were now 242 members, as compared with 239 last year.

At a subsequent stage of the proceedings, a statement of the accounts of the Treasurer was made by the Auditor, Mr. D. Bruce Peebles, of Edinburgh. It was considered highly satisfactory; and both the Treasurer and the Auditor were cordially thanked for their services.

The Secretary also submitted the names of the members who had resigned or had died during the past year; and he likewise submitted applications from eight candidates for election as ordinary members, and three extraordinary members, together with four as associates.

PRESIDENT'S OPENING ADDRESS.

The Inaugural Address of the President was not of any great length, or comprehensive, in the ordinary sense of that term; but it was eminently interesting, pointed, and instructive. As the present issue of the JOURNAL contains the text of the address, it is not necessary to give any detailed summary of it. One topic of marked importance was the information which Mr. Terrace was able to give, in summary form, from the "Statistical Reports" (the origin of which was due to the now defunct West of Scotland Association of Gas Managers, and the publication of which was continued by the North British Association)—namely, that the annual make of gas, which was about 6008 million cubic feet in 1883, had risen to about 7133 millions in 1887; thus showing an increase of about 18·7 per cent. in five years. Considering the close connection which Mr. Terrace (under Mr. Foulis) has had with the working out of the regenerative system of retort firing at the Dawsholm Gas-Works, it was but natural to expect that he would have something of interest to say upon the subject. In the course of his remarks on it, he stated that there were now some fifteen gas-works in Scotland where the retorts are worked on the regenerative principle—making 3410 million cubic feet of gas per annum, or equal to 47·8 per cent. of the total manufacture. He further stated that if those works were taken into account where regenerative firing was contemplated, there would, in a short time, be manufactured in retorts heated by regenerative furnaces nearly 60 per cent. of the gas produced in Scotland. As regards choked ascension-pipes, Mr. Terrace mentioned that stopped pipes were not mere numerous with regenerative settings than with ordinary furnaces, notwithstanding the fact of the temperature of the retorts being much higher. The question as to the requisite temperature to which gas should be brought in the condensers before scrubbing and purifying take place received some consideration at the hands of the President; and his remarks upon it were very instructive, and might with advantage be studied by many of our readers. Owing to the very suggestive paper which Mr. William Young submitted to the Association at the meeting held in Stirling a year ago, Mr. Terrace was in duty bound to refer to the question of the purification of gas in closed vessels; and from the tone of his remarks we may confidently expect that the Sub-Committee of the Association, in co-operation with Mr. Young, may be able at next year's meeting to contribute a report of much scientific and practical value. A question of growing and very vital importance in connection with the gas industry is that of using mineral oil instead of coal as the raw material for the production of illuminating gas. This was also touched upon in a very effective manner by Mr. Terrace; and our readers will do well to peruse his

remarks upon it. How to get gas consumers to burn the gas supplied to them in such a way as to obtain something like its photogenic value is a question of great importance, and of perennial interest; and on this matter Mr. Terrace made some suggestive remarks. He also gave some exceedingly interesting data bearing upon the results obtained by testing various types of regenerative lamps with gas of different qualities. In the course of his concluding remarks, he referred to the excellent opportunity which members of the Association had in the Glasgow International Exhibition for inspecting and making acquaintance with some of the latest novelties, and some of the best apparatus in use for lighting, cooking, heating, and motive power; and he had no hesitation in saying that gas was still able to hold more than its own for brilliancy and applicability of the latest forms of light, even though confronted on nearly every hand by its would-be rivals, mineral oil and electricity.

Mr. A. Macpherson (Kirkcaldy), in proposing a vote of thanks to the President for his address, said that he thought Mr. Terrace had refuted the assertion that gas engineering had made little or no progress during the last twenty or thirty years. If they would only consider the question of burners, he was perfectly certain they would confer great benefits on the consumers of gas. And if the consumers themselves would give some little consideration to burners, they would certainly save their pockets to a very large extent.

GAS-BURNERS FOR PHOTOMETRICAL PURPOSES.

This was the first subject taken up in the programme of papers provided by the Committee of the Association. It was dealt with in a paper by Mr. Geo. R. Hislop, of Paisley, who stated that its consideration was the result of an obligation which he had come under to the Committee to dispose of a remit made to a Special Committee of the Association appointed three years ago for the purpose of determining the best standard burner for Scotch gas. After most exhaustive experiments which he had instituted, he had found that nearly all the burners manufactured had their orifices drilled at angles ranging between 45° and 60°, and this apparently without regard to quality of gas; whereas the investigations and the experiments which he had carried out unmistakably proved that the angle at which the holes of burners stood to each other had a remarkable influence on the quality of the gas. The principle which he had endeavoured to lay down (as will be seen from the text of the paper, appearing on p. 205 to-day) was that by the elongation of the flame as the scale of quality of the gas was descending, they secured what was equivalent to a reduction of pressure at the point of combustion of something like 2-10ths of an inch by increasing the period of incandescence of the carbon atoms, and this while fulfilling the requirements of the law in having a pressure of 5-10ths of an inch. A properly elongated flame could not be obtained from a jet drilled at the usual angles unless the gas was consumed at a pressure far below the requirements of the Acts of Parliament, and then a smoky flame would result. Mr. Hislop's paper excited peculiar interest; the general feeling of the members being that he had started on a new departure in reference to the construction of burners, and the suitability of different types of the same for different qualities of gas.

The discussion which arose on the paper was commenced by Mr. Foulis, who said that it could scarcely have been anticipated that burning gas under the same pressure and in the same quantity would have shown such very different results as the angles of the holes varied. The information was important, he said; and it showed that, in making comparative statements of different qualities of gas, it was very necessary to know the conditions under which the gas was being burned. It also showed how important it was that consumers should attend to getting proper burners to develop the full photogenic value of the gas; and that those who were in charge of gas-works should endeavour to educate consumers as far as possible, and see that the burners that were supplied to them were the proper ones for the quality of the gas manufactured in the different towns.

Mr. D. Bruce Peebles followed in the same strain of remark, and readily admitted that Mr. Hislop had brought out a very novel element as to the angles at which the gas issued from the burners. He pointed out that Mr. Stewart, of Greenock, had some time ago shown that each type of burner seemed to have its own idiosyncrasy, as each human being had. He urged that different pressures should be used along with burners having different angles in the orifices. After making a few remarks of a humorous character regarding the "gas-burner man," he spoke of the great importance of the subject which had been taken up in the paper, seeing that there was an enormous waste of gas through using bad burners.

Mr. Key directed attention to the fact that the internal diameter of the barrel of the burners ought also to be taken into consideration, inasmuch as in the old iron burners the tubes were very narrow, while in Bray's burners, which were now so extensively used, there were very wide tubes; thus giving a great amount of heating surface.

Mr. D. M. Nelson remarked that the tests carried out by Mr. Hislop had all been made with iron burners, whereas such things were now scarcely ever used.

Mr. Macpherson spoke of the paper as being altogether novel; and as it needed thinking over before it could be properly discussed, the author must excuse the members for not dealing with it as its merits warranted. He too admitted that the size of the burner barrel was a matter of great importance.

Mr. John McCrue regarded the treatment of the subject as

being altogether unique, and he urged that gas consumers should be educated to the proper use of their gas-burners, as it was the desire of every gas manufacturer that the gas should be burnt well, so that the consumers might be pleased. He also urged that burners suited for the different levels of a town should be kept and given to the consumers for ordinary use. That was a thing, he believed, which Mr. Hislop had attended to in his town.

Mr. Hislop made a suitable reply to the various remarks that had been offered, being glad to know that his paper had excited so much interest.

MANUFACTURE OF SULPHATE OF AMMONIA.

A short paper next followed, the author of which was Mr. R. Cowie, of Tillicoultry, who gave a plain and interesting account of a year's experience of the manufacture of sulphate of ammonia. In the course of his remarks, he explained the steps taken for the erection of the plant at the works where he was employed, so that they might themselves be enabled to work up the ammoniacal liquor into sulphate of ammonia. He stated that the process had not interfered very much with the ordinary work, even during the busy season. From 836 tons of cannel coal used in the past year, he had obtained 8 tons 17 cwt. of sulphate of ammonia. The sum received for the quantity sold amounted to £101 9s. 7d.; and after paying all expenses, and allowing a percentage on the capital used, there was a surplus of £59 3s. 1d. He stated that most of his produce had been sold in the district, and had not caused them any trouble.

The discussion which followed was quite as interesting as the paper itself had been; and the speakers generally acknowledged their indebtedness to Mr. Cowie for having shown that the manufacture in question could be carried on economically in small works such as those at Tillicoultry. Various suggestions were made to Mr. Cowie and to other managers who might think of following his example. The paper also received a little friendly criticism from one or two of the speakers. In his reply, Mr. Cowie stated that they were selling their tar; and that for two or three years they were getting for their residuals only 5½d. per ton of coal carbonized, whereas they were now getting 2s. 10d. per ton.

TAR AS FUEL FOR STEAM BOILERS.

Mr. John M'Crae, of Dundee, read a paper on "Coal Tar as Fuel for Steam-Boilers." He explained that the sudden fall which took place in the price of secondary products about three years ago forced gas manufacturers to look around for some better markets for their products. While boiled tar could readily be disposed of at several of the German ports, the expense and difficulty of loading ships took so much from the saving derived, that it occurred to him to look nearer home for a remedy. He had, therefore, made experiments to ascertain the relative value of coal and tar. The coal which he employed was what is known as Strathavenhouse small coal, which costs in Dundee 5s. per ton delivered. The experiment in each case lasted for 48 hours. The tar employed was "boiled" tar; the naphtha having been previously removed, but the pitch oil left in the tar. In Dundee the value of the tar was about 4s. per ton. The result of the experiments was as follows:—Coal, 10 tons 16 cwt., at 5s. per ton, £2 14s.; tar, 1400 gallons (9 tons 3 cwt., 160 gallons = 1 ton), at 4s. per ton, £1 16s. 7d.; saving per day by using tar, 17s. 5d. This was on the longest day, when they were using a mere fraction of steam as compared with their winter requirements. Consequently the profit was proportionately less than it would be when they were in full work. Mr. M'Crae explained, in detail, the working of the apparatus used in producing the results mentioned; and he stated that in the tar furnace tar only was burned. He also pointed out that in some districts even better results could be obtained, as in many country towns the coal could be had for 2s. less per ton than in Dundee, and that for the tar for which Dundee was receiving 4s. per ton they would get double this sum. In concluding, he said that there was a future for liquid fuels, such concentrated fuels as crude naphthas, paraffins, and pitch oil; and he referred particularly to the importance of such an application as the employment of these products for steam-boilers—land, locomotive, and marine.

This paper also led to an instructive and interesting discussion; the speakers being Mr. Sutherland, tar distiller, of Falkirk, Mr. Hislop, Mr. Macpherson, and Mr. Key.

At this stage the members adjourned for luncheon. After the meeting had been reconstituted, the President announced that the result of the scrutiny of the balloting-papers was that Mr. Hislop had been elected as President for the year 1888-9; Mr. S. Stewart (Greenock) and Mr. R. Robertson (Bathgate) as Vice-Presidents; Mr. R. S. Carlow as Secretary and Treasurer; Mr. D. Bruce Peebles as Auditor; and Messrs. J. M'Gilchrist (Dumbarton), J. Adam (Pollokshaws), and T. D. Hall (Montrose) as Members of Committee. Dunfermline had been selected as the place for next year's meeting.

AUTOMATIC GAS LIGHTING.

A short but very valuable paper on this subject was submitted by Mr. G. Keillor, of Nairn, who described what he claimed to be an improved system of lighting gas by means of an electric spark, and which he has had in operation for some time for lighting the pier at Nairn. By the aid of a working model, he explained the system of lighting; showing how the gas pressure, by means of a governor combined with an electric lighter, operated in automatically lighting the lamps. By his system the lighting of a town could be regulated from the gas-works, and the whole of the rows of lights manipulated from one battery. It would also be found convenient at railway stations, in factories, and similar places.

In the discussion which followed, Mr. Keillor was warmly complimented on the ingenuity, the economy, and the success of his arrangements; Mr. Macpherson remarking that gas managers did well in turning electricity—their great rival—to account in those circumstances where it was specially serviceable. The President and Messrs. Hall, Stewart, Smith (Aberdeen), Cheyne (Briton Ferry), and Key also took part in the discussion.

SELLING GAS.

This subject was dealt with in a very lively and humorous manner by Mr. James M'Gilchrist, who, in the course of his paper, described an ideal gas company of the future, which would canvass vigorously for business, on the system which is common in ordinary commercial pursuits. The company, he said, would supply gas of high illuminating power, and free from all impurities. It was a mistake to lower the illuminating power for the purpose of cheapening the gas. The public did not grumble at the price of the gas so much as at the bad light. His ideal company would also look to the piping and lighting arrangements within the houses of their customers. They would also abolish the rent for meters; and would introduce a system of payments as approximate as possible to the ready-money system. In the next place, they would protest against the iniquitous system of valuing gas-works now pursued by assessors, and which militated against the selling of gas. They would adopt the co-operative system of making consumers shareholders. This could, he said, be accomplished by a graduated system of deposits according to the number of apartments in each customer's house. Finally, gas corporations would not take gas profits in payment of rates which ought to be paid by the rate-payers at large. The day was soon coming when these taxes would be abolished, and gas sold at as near cost price as possible. In the course of his remarks, Mr. M'Gilchrist showed one of Messrs. W. and B. Cowan's automatic gas-meters, by means of which a certain quantity of gas can be paid for beforehand.

The discussion which followed turned to a considerable extent upon the question of deposits by consumers and the use of meters free of charge. One speaker was in favour of small and frequent payments; and would not press the deposit system too hard. He would also have the meters supplied free. Another said he would not supply free meters; and that in his town the Gas Commissioners are very easy as to the deposits—the result being that they did not lose more than ¼ per cent. on their total revenue. Then a speaker expressed himself in favour of monthly accounts, and said his usual practice was to exact a deposit of 5s. until the second account was paid. About half-a-dozen members spoke in the discussion; and in his reply Mr. M'Gilchrist threw out the suggestion that the Committee of the Association should bring up a report on the subject at the next meeting. He remarked that the practice in Dumbarton for the last dozen years or so had been that all the gas-pipes introduced into new houses were under the inspection of an officer of the Gas Trust. He was specially strong on the question of abolishing meter-rents, while recommending that the deposit system should be universally applied, and that the consumers should be allowed interest on their deposits.

REGENERATIVE FURNACES FOR SMALL GAS-WORKS.

Mr. J. Smith, of Rosewell, gave a short paper descriptive of a regenerative furnace which he had devised and worked out to a successful issue about a year ago, and which he had since improved upon. This short paper excited a discussion of considerable interest, inasmuch as the author had done, in the language of Mr. Smith, of Aberdeen, "a very smart thing." Mr. Stewart characterized the arrangement as a highly ingenious one; and other speakers also made complimentary remarks regarding it.

SCRUBBING, CONDENSING, AND WASHING COAL GAS.

Mr. W. Key read the concluding paper, in which he described a process for the elimination of the tarry particles in the gas after leaving the hydraulic main. In this apparatus (which he described, and which was fully illustrated by large diagrams), there is a dry scrubber having revolving arms fixed on an upright centre shaft, and by the velocity of these arms the gas is thrown against corrugated sides of the scrubber, the tarry particles being eliminated.

In the discussion which arose after the paper was read, some complimentary remarks were made by two or three speakers, and by others the system described by Mr. Key was severely criticized. The author was not able to say that the system had been put into practice, and the conclusions, therefore, were regarded as purely hypothetical.

This closed the ordinary business on the programme; and, in drawing the proceedings to a close, the President, on behalf of the meeting, thanked the authors of all the papers. Then Mr. M'Crae, on behalf of the Association, presented the gold medal of the Association to Mr. Terrace, the retiring President, who replied in feeling terms. The Revisal Committee was appointed; and, finally, on the motion of Mr. Hislop, a very cordial vote of thanks was awarded to the Secretary, Mr. Carlow.

The members then adjourned to the International Exhibition; and at six o'clock sat down to dinner, with their lady friends, in the Royal Bungalow. Mr. Terrace presided, and the vice-chairs were occupied by Messrs. Hislop, M'Gilchrist, and Carlow. Dinner over, the company at once dispersed over the exhibition, where they spent the remainder of the evening.

On the following day the annual excursion of the Association took place—by railway to Balloch, at the lower end of Loch Lomond, then by steamer up the loch to Tarbet, luncheon being served in the Tarbet Hotel; a drive or walk of about two miles to

Arrochar, and then by boat down Loch Long to Dunoon, where tea was partaken of; and lastly by steamer to Craigendoran, where train back to Glasgow was obtained. For the greater part of the day the weather was almost all that could be desired, and the members and their friends enjoyed themselves very much; and thus ended what will be regarded as the most successful meeting yet held by the North British Association of Gas Managers.

PRESIDENT'S INAUGURAL ADDRESS.

Gentlemen,—I thank you for the honour conferred upon me in electing me to preside over your deliberations at this our Twenty-seventh Annual Meeting.

There are now no fewer than nine similar Associations to this in Great Britain. Three of these are what may be termed "National," and six "District" Associations. These, and others on the Continent and in America have all sprung into existence since the year 1862, when the North British Association was instituted. The kindred Associations are doing good work in holding meetings, and otherwise disseminating very valuable information; each benefiting the other by publishing their reports, which are found of great service in our every-day work and transactions.

Taking our "Statistical Reports" as the basis of information, Scotland, I find that the make of gas in the year 1883 was about together with that from other sources regarding the gas supply of 6008 million cubic feet, and in last year (1887) about 7133 millions; showing an increase in five years of 18·7 per cent.

Although, in one sense, the process of gas manufacture may be said to be similar in its essential features to that so freely given to the world by Murdoch 80 years ago, it must be acknowledged that Science has greatly developed his ideas. Who, even ten years ago, could have foreseen that triple the carbonizing work would be done with the same floor-space in the retort-house, and that three times the illuminating value would be obtained from the same quantity and quality of gas? These vast improvements are due to the regenerative, or, as it is sometimes called, the recuperative principle—*i.e.*, regaining and utilizing the heat that otherwise would have been lost in the old open furnace, and in the combustion of the open gas-flames respectively. It is principally due to these and other such inventions, that coal gas will hold its position in the supply of artificial light for many years to come.

I need not recapitulate the many advantages derived from the use of regenerative retort settings; but I may say that the expectations formed when the system was introduced have been realized. The only development that I will notice here is the increase in the size of the retorts with the same oven space. The benefit that accrues from this is shown in that each retort can now carbonize 22 cwt. of coal per day, in the 21 in. by 15 in. size, as against 18 cwt. in the 18 in. by 13 in. size. Before this system was applied, it was only possible to carbonize 14 cwt. per retort per day in the 18 in. by 13 in. size. If you reckoned that eight retorts are now placed in one oven where there were only four to six in the old furnace arrangement, and that half the fuel is saved, you can estimate the great amount of carbonizing power and economy attained. Doubtless, in the course of a few years, the system will be more generally adopted than it is at present. There are about fifteen gas-works in Scotland, where the retorts are heated by this method, making about 3410 million cubic feet per annum, equal to 47·8 per cent. of the total manufacture; and if we take into account those works which contemplate introducing the new furnaces, nearly 60 per cent. of the gas produced will in a short time be manufactured in retorts heated by regenerative furnaces.

Judging by the frequency with which the subject of choked ascension-pipes is discussed, it would appear that these are always to be a source of annoyance. My experience is that stopped pipes are not more numerous with the regenerative settings than with the ordinary furnaces, although the temperature of the retorts is much higher. Pipes will choke in any setting, if the retorts are not evenly charged, and the liquid in the hydraulic main kept thin, to give as slight resistance as possible to the issuing gases.

The question as to the requisite temperature to which the gas should be brought in the condensers, in order to secure its proper after-treatment in the scrubbers and purifiers, is a most important one. The ever-changing temperature of the atmosphere, and the varying quantities of gas made, necessitate having a ready means whereby to regulate the cooling power. This requires constant supervision. I find that a continuous temperature of about 65° Fahr. is the best for the gas at the outlet of the condensers; but, although we may be able to control the temperature up to this point, it is next to impossible to guard against the effects of low temperatures on the scrubbers, purifiers, and gasholders; also of very severe cold on the street-mains, necessitating the use of increased quantities of high-class candle, in order to maintain a uniform quality of gas. To show how the different qualities of coal vary according to the seasons of the year, I may mention that when the temperature of the air is normal—say, 60° Fahr.—we can use coals, with good heats (say, about 2000° Fahr. in the retorts), and three-hour charges, giving an average illuminating power of 23 candles to maintain the standard quality of 23 candles; but when the temperature falls to 45° and 30°, it is necessary to use coals that will yield gas of 24 and 25 candles respectively at the normal temperature, in order to keep up the standard. These figures form a great contrast to those where 16 to 18 candle gas is supplied, as, in these circumstances, the average quantity of first-class coal used in midwinter does not exceed

5 per cent., and not more than 2½ per cent. on the yearly quantity; whereas, when 23-candle gas is supplied, it is found that in midwinter 20 per cent. of the higher class candles are required, and about 11½ per cent. in proportion to the yearly quantity. This proves that the higher the quality of the gas, the more it is subject to depreciation from atmospheric influences. It is, therefore, evident that great portions of the luminous properties of the gases are deposited in the apparatus between the retort and the consumer; the quantity depending on the quality of the gas supplied, and on the degree of cold to which the gas is subjected; and unless the extent of this is ascertained by frequent photometric testings daily, the consumer cannot be supplied with gas of uniform quality.

I need scarcely say that the scrubbing power should be sufficient to free the gas from ammonia; but it should not be taken for granted that, because there are no indications of this impurity at the outlet of the scrubbers, the gas must necessarily be free from ammonia when stored in gasholders. It is quite possible to have gas free from ammonia at the outlet of the scrubbers, yet containing ammonia in considerable quantity at the outlet of the purifiers, as a chemical reaction may take place, probably due to a decomposition of cyanides by the lime used in purification. When this occurs, means should be taken to absorb the ammonia before the gas enters the holders. Very wet lime is conducive to more, rather than less, ammonia being formed. The hydrate should not contain more moisture than 50 per cent. of its weight.

The purification of gas in closed vessels by means of the foul gases contained in itself, so far as its application to practical work is concerned, is still untried. It is unfortunate that arrangements have not been made to investigate the system advocated by Mr. William Young, who read a paper, and ably demonstrated his process at our last meeting. Apparatus on the Clans system has been erected at Belfast sufficient to purify gas from 250 tons of coal per day. This is expected to be in operation during the ensuing winter; and the results will be looked forward to with much interest. These two systems are now before the gas world; and I need only refer you for a full description of them to the past records of the various Associations. I trust that, before the expiration of another year, apparatus will be at work, showing the operation of Mr. Young's process on a practical scale; so that we may be in possession of actual data in regard to the cost of plant and working, and other necessary information, and also the relative advantages likely to be derived from employing each system.

The use of oil as a substitute for coal in gas making has again been receiving attention; the very high luminosity of the gas appearing to be considered as one of its principal advantages. This, however, is only one side of the question; and it may be conceded that we, as producers of light, are alive to the merits, or otherwise, of employing oil in our manufacture. The system may be suitable where a supply of coal gas at a moderate price is not available; but it will not be generally adopted until the "steady" price of the raw material makes it more profitable to use than coal. Even then the introduction of oil would require to be very gradual, as its use in gas-works, if only to a limited extent, would tend to greatly raise the price. The gas from oil is generally credited with being of 60-candle power. This may be the case when made and tested on the spot; but when it has to be stored and distributed in the usual manner to towns, the results may be vastly different. From practical tests made on oil gas after storage (the temperature of the gas being 48° Fahr.), I found the quality to be 37 candles, per 5 cubic feet, with a consumption of 2½ cubic feet per hour with one of Bray's No. 4 union-jet burners. When the same gas was tested with a No. 3 burner, consuming 2 feet per hour, the quality was found to be 29 candles, calculated to 5 feet per hour; making it apparent that the use of small burners is as injurious to gas of this comparatively high quality as to gas of lower illuminating power. The question arises: Is 60-candle power gas worth twice 30-candle gas, or thrice 20-candle gas? I think not. The greater pressures at which the higher qualities have to be consumed, in order to get the best photogenic results—say, from 10-10ths to 14-10ths—eject the hydrocarbon particles from the burner into the atmosphere at such a rapid rate that a quantity of them pass off unconsumed; whereas, with the lower qualities consumed at lower pressures—say, 5-10ths or 4-10ths—a greater proportion of the light-giving properties are utilized.

It is one of the most difficult problems how to get consumers to use the gas supplied to them properly; this being at the root of most of the complaints they make about the light obtained. It should be more generally known that the amount of light emitted depends as much (if not more) on the means of consumption as on the inherent quality of the gas. I trust some of the papers to be read to-day will touch on this subject. So much has already been said and written on the great waste of gas, and still so much has been left undone that the field for improvement in this respect is nearly as wide as ever. Until it is in the power of the companies and corporations to take charge of the gas supply from the meter to the point of consumption, nothing of any benefit is likely to accrue to the consumer.

In testing several of the devices intended to improve the ordinary open gas-flame, I found no increase in the luminosity per cubic foot of gas consumed from that given by the union-jet consuming 5 feet per hour at 5-10ths pressure. The inventors of most of these devices start on a wrong basis by first using small burners, thus forcing the gas through minute apertures at high pressure, and then baffling the flame at the point of ignition, instead of

regulating the pressure, and using the gas through a large burner. Although apparently a very simple matter, it seems a very difficult one to be understood, or acted upon, by the average consumer—that any ordinary burner (union-jet or batwing) provided it be the size suitable for the space to be lighted, is as good as any other (open flame), if used at the proper pressure, for the quality of the gas. When consumers cannot adjust the burners and pressure, they should, in order to obtain a good and economical light, use gas-governors (where the fittings are suitable), or burners containing within them the means for regulating the supply.

From the results of about 100 tests made on 23½-candle gas, to ascertain the relationship between the durability test and the candle power, I found (with a 5-inch flame from a single-jet burner, consuming, at 0.59 inch pressure, 1.204 cubic feet of gas per hour corrected for temperature and barometer), that the durability in minutes, divided by 2.117, gave the quality in candles. About half the number of tests ranged to 1.39 candles above, while the remainder varied to 1.36 candles below, the average results obtained by the Lethaby photometer. Considering that candles themselves may vary to a similar extent, these results would show that within certain limits the readings from the durability test may be relied on when the same class of coals and other conditions of manufacture are constant. Using the same divisor for other gases, however, I found variations of 3 to 4 candles above the actual quality, which can only be accounted for by altered conditions of manufacture. From these data we may infer that to use the durability test as a standard, it would be necessary first to obtain a factor from a series of experiments similar to the above, with comparative daily readings over a long period. We may also conclude that the same sources of error present themselves in the use of such appliances as the jet photometer.

Comparing the results obtained by testing seven types of regenerative lamps with various qualities of gas, I find the proportion of increase in light from that given by the usual test burner varies from 100 to 150 per cent. The following table gives the results of some of the tests made:—

The Illuminating Power of Various Burners (the Regenerative Lamps being at an Angle of 45° to the Candles).

No. 8 Union-Jet Burner (for Cannel Gas), consuming 5 ft. per Hour at 5.10ths Pressure.	No. 8 Union-Jet Burner (for Common Gas), consuming 5 ft. per Hour at 3.10ths Pres.	London Standard Argand.	Regenerative Lamps. "A" Series.	Regenerative Lamps. "B" Series.

7.02	—	13.84	—	29.45

It is generally conceded that the different qualities of gas ought to be tested in the burners best adapted to yield the highest photogenic results. Where there is no clause in the Gas Act determining the mode of testing, we may soon be having it reported that the gas supplied to certain towns is of abnormally high power—say, "50-candle gas," as shown by the photometer with the best burner, or, as some Acts put it, "the most suitable burner." When the quality of gas is stated as of such a candle power, it should, by way of comparison to that supplied by other towns which have to use the prescribed, or recognized standard burner, be mentioned as tested by a certain defined burner. This is now rendered all the more necessary on account of the introduction of incandescent burners and regenerative lamps.

In the Gas Annex of the Glasgow International Exhibition, the opportunity is afforded us of inspecting some of the latest novelties, and some of the best apparatus, in use for lighting, cooking, heating, and motive power. It will be observed that gas is still able to hold more than its own for the brilliancy and applicability of the latest forms of the light, although confronted on nearly every hand by its would-be rivals—oil and electricity. Gas lighting is applied wherever reliability is a *sine qua non*; and it is therefore ever ready to take the place of, and, when need arises, make good the defects of its luxuriously nurtured brother. The Machinery Department will also be of special interest to the members; and there, as well as in a great many other departments, the gas-engine—in its various forms—plays a very important part. Altogether we have reason to congratulate ourselves on the great success of the exhibits where gas is employed, as well as to the many useful purposes to which it so readily adapts itself. Its motto is always: "Ready, aye ready."

GAS-BURNERS FOR PHOTOMETRICAL PURPOSES.
(REPORT ON THE REMIT ON THE BEST STANDARD BURNER FOR SCOTCH GAS.)

By GEO. R. HISLOP, of Paisley.

The consideration of this subject is the result of an obligation which I have come under to your Committee, to dispose of a remit to a Special Committee of this Association appointed some three years ago, and of which I have recently been made a member, to determine "The Best Standard Burner for Scotch Gas." The title of this paper may justly excite surprise, and exact the enquiry why light is needed on such a subject, after an experience of three-quarters of a century of practical lighting by coal and cannel gas.

It cannot be denied that in the midst of abounding light on all possible questions affecting gas manufacture and distribution, we have been comparatively slow to discover the laws which regulate the elimination of the highest lighting power of different qualities of coal and cannel gas. Inasmuch as it is just within these last few years that we have been able to hail some dawning light, and now we have but entered upon a new era in the history of gas illumination, by the discovery of means whereby we are now enabled to realize, approximately at least, the highest possible lighting power of the gas. I refer to low-pressure combustion, and the utilization of the radiant and conducted heat of such combustion in the so-called regenerative gas-lamps. These are, moreover, entirely a new departure in gas lighting. But with respect to the common form of burners, while various improvements or devices have been introduced for the purpose of reducing to a minimum the pressure at the point of combustion, and with a corresponding increase in light—chief amongst which may be mentioned the ingenious automatic "Needle" governor burner—no attempt has been made to show that intensity is affected in any way under any other condition. The fact is well established that a low velocity *versus* slow combustion of the issuing gas from a burner, has an important effect upon the value of the light afforded by any quality of gas; but no definite rule has ever been laid down to enable anyone to order or procure a burner or burners exactly adapted for any particular quality of gas. Not one word of reference is ever made to the angle of the impinging jets or to relative dimensions of flame in relation to quality of gas, which I maintain are indispensable conditions. A flame even at 5.10ths of an inch pressure may be unduly spread; and this, in the case of gas of poor quality, is to expose it to over-oxidation, and the cooling effect of the nitrogen of the atmosphere, with its consequent reduction of light.

I purpose in this paper to define certain principles in the construction of burners, which have hitherto been disregarded generally, but which I hope to show are all-important in their bearing upon the quality of the gas. It is not my intention to do more than touch upon the subject of burners for domestic and public lighting; but simply to deal with the class of burners which we may or are compelled to employ under existing Acts of Parliament for the purpose of determining the highest illuminating value of the gas we deliver to the consumers, consistently with the conditions laid down in said Acts of Parliament. It will be borne in mind that one invariable condition is that "the pressure at the point of combustion shall be equal to 5.10ths of an inch;" hence all my results must necessarily be based on this hypothesis.

That our information is defective on the subject of suitable burners for testing various qualities of cannel gas will, I feel certain, be testified to by all careful experimentalists and gas managers who have to deal with gas of 20-candle power and upwards, and which is invariably tested by means of union-jets. Moreover the fact that this Association and your Committee have realized the difficulty, will itself justify the enquiry. Indeed I confess that for many years it has been a matter of considerable concern to me how or where to find burners of proper construction for different qualities of gas. When found it was purely accidental, and they were consequently prized as if worth ten times their weight in gold. Since having no definite theory regarding the construction of such burners, to order their manufacture was, of course, out of the question. I have in my experience, therefore, tried to bring to proper condition by stuffing, in various ways, all sizes and forms of burners I have been able to lay my hands upon; but general failure has been the result. But why should I succeed when the construction of the burners tried were entirely at variance with the conditions requisite to develop the lighting power of the gas? In short, the orifices of all the burners were drilled at angles much too high for the quality of gas I wished to test. Nearly all burners manufactured have their orifices drilled at angles ranging between 45° and 60° (and that without regard, apparently, to the quality of gas at all); whereas the investigations and experiments I have carried out unmistakably prove that the angle at which the holes of a burner stand to each other have a remarkable influence upon the quality of the gas. Suppose we take 22½-candle gas, the angle giving the highest intensity of light is 22°; but if the same volume (5 feet) be consumed at 45°, the illuminating power will be reduced to 19.71 candles, or 0.110 of a candle for each degree advanced; while the dimensions of the flame will have been altered from 3½ inches high by 2½ inches broad to 2½ inches high by 3½ inches broad. The table (on next page) will show similar results for all qualities of gas from 17.9 to 32.6 candles, advancing approximately 2 candles in quality for each series of tests.

In order to arrive at the results thus shown, I had specially made for the purpose of my experiments an extensive series of burners—consisting of sizes Nos. 5, 6, 7, and 8, drilled at the various angles up to 60°; but my experiments clearly proved that the No. 7 size afforded the best results for all qualities of gas. Hence I have given the results from that size of burners only. These burners were of iron, but carefully made, and without any stuffing or pressure-reducing medium save the smallest quantity of cotton-wool to prevent flaring, balance the flame, and give 5 feet per hour exactly at 5.10ths inch pressure. The illuminating power was carefully tested at the various angles, noting at the same time in each case the exact length and breadth of the flame. The latter, however, I have not given on the table, as not being absolutely necessary; but the connection between the angles of the jet orifices, the dimensions of the flame, and the illuminating power, is very marked.

The principle which I have endeavoured to lay down is that, by the elongation of the flame as the scale of quality of the gas is descending, we secure what is equivalent to a reduction of pressure at the point of combustion, of something like 2-10ths of an inch, by increasing the period of incandescence of the carbon atoms, as anyone may readily suppose would be the result in an elongated flame; and this while fulfilling the requirements of the law in having the pressure at 5-10ths inch (no reference being made in the Acts to the dimensions of the flame). A properly elongated flame cannot be obtained from a jet drilled at the usual angles, unless consumed at a pressure far below the requirements of the Acts of Parliament, and then a smoky flame would result.

It will be observed from the table that the necessary angle for the lower qualities of gas increases rather slowly as compared with that required for the higher qualities of gas; and it will be obvious to all that, by ascending the scale of quality, a corresponding increase of angle and more direct impingement of the issuing gas, will be necessary to burn 5 feet and secure the highest results, which, as a matter of course, is just under the smoking point. Conversely, by descending the scale of quality, the angles must be reduced, and with this a gradually narrowing flame, till we should reach for the 5 feet consumption a round flame like that of a rat-tail burner—the diameter of the burner tip cup being, of course, narrowed with the narrowing flame. Thus the principles I have laid down may be represented by two lines drawn from a point, the point representing gas of the value of say 5 candles with a solid flame, and gradually diverging till representing the diameter of the flame of gas of the highest intensity, or say 32·6 candles at an angle of 45° (as per table), and which gives 3½ inches as the breadth of the flame (by 3½ inches high). Thus, in gradually rising or descending the scale of quality, I contend that the diameter of flame giving highest intensity for different qualities of gas will fall within these converging lines.

With regard to burners made on this principle for ordinary lighting, it will be necessary only to obtain them at angles of say from 5° to 7½° higher than those giving the highest intensity for photometrical purposes—depending upon whether for domestic or factory use.

I might have said much more upon this important subject, but I trust I have made sufficiently clear to you the principle upon

which burners for all qualities of gas ought to be constructed; and if so I shall have discharged my obligation to your Committee to dispose of the remit "On the Best Standard Burner for Scotch Gas."

Register of Patents.

GAS-LAMPS.—Gordon, T., of Philadelphia, U.S.A. No. 11,698; Aug. 29, 1887. [8d.]

The object of this invention is to construct a gas-lamp that may be exposed to the varying conditions of the atmosphere without serious disturbance of the flame.

In the accompanying illustration, A is the burner; and B, an approximately air-tight chamber surrounding it. C is the escape flue of the burner; D, an air-tight chamber surrounding the escape flue; E, air tubes connecting the chamber B with D; and F, air tubes extending upwards from D. G are partition plates which may extend downward within the air tubes F; H are caps or plates which rest upon, or may be attached to the upper ends of the partition plates G; and I is a wind cap attached to the escape flue of the burner. Surrounding the flue C, is arranged a flue K, open top and bottom; air being allowed to circulate between the flues to prevent radiation of heat to the tubes E, also to prevent the cooling of the flue by sudden blasts of cold air.

When the burner is in operation, the waste products pass up through the flue C, producing a draught and causing the cold air to circulate downward through the passages E, and thence (as shown by the arrows) through the regenerative chambers of the burner. The object of this form of construction is to overcome the principal difficulty experienced with lamps in which the inlet and outlet are at opposite ends of the fixture—viz., the reversal of the draught in the escape flue, caused by gusts of wind sweeping past the inlet. The suction on the inlet is balanced by the arrangement of the partition plates within tubes F. From whatever direction the wind may blow, air is taken in on one side of the plates, to compensate for that drawn out on the other side.

To facilitate the lighting of the burner, and to prevent the circulation from being started in the wrong direction, a cone L is employed, which makes a tight joint with the chamber B above the air inlet. The top of the cone approaches the edge of the discharge cone M, so as to form a species of reducing nozzle or injector, which discharges through suitable openings round the base of the pipe C, and thus tends to create an up-draught through the discharge cone M and escape tube C. To prevent down gusts of wind in the escape tube, and to maintain an even discharge therefrom (and consequently an even flame within the lamp), the wind cap is made small enough in diameter to allow of only about half the waste products escaping at the top, while the rest should pass out at the bottom, as indicated by arrows. This throttles the suction without impeding the draught, and prevents any violent fluctuation of the flame.

VALVES FOR LIQUID METERS.—Barton, C. C., of Edinburgh. No. 11,699; Aug. 29, 1887. [8d.]

In patents No. 1561 of 1883 and No. 2876 of 1885 are described certain water meters designed by the present inventor; and in patent No. 4029 of 1887 improvements in the construction of liquid meters are detailed—part of such improvements relating to the construction of valves used therein. The present invention relates to further improvements in such valves; but the description is not intelligible apart from the specifications of the three earlier inventions.

GAS-MOTOR ENGINES.—Abel, C. D.; communicated from the Gas Motoren Fabrik Deutz, of Deutz, Germany. No. 12,187; Sept. 8, 1887. [8d.]

This invention relates to the construction of engines worked with combustible gas and air compressed previous to entering the engine cylinder. The principal feature of novelty is the method employed for forcing the combustible gas and the air separately into a reservoir, in such manner that they are only in contact over a very limited surface, so as not to mix to any practical extent. The inlet for the gas is situated near the inlet port of the cylinder, so that when this port is opened the gas enters first into the cylinder, and then the compressed air; the two mixing in the cylinder to form a combustible charge.

WOOD GRIDS FOR GAS-WORKS PURIFIERS.—Lowe, E., of Rowley Regis. No. 3159; March 1, 1888. [8d.]

Purifiers constructed according to this invention are made entirely

of wood, so as to minimize their liability to deteriorate through the action of the gas passing through the purifiers. The wooden bars of the grids are arranged parallel to each other, and maintained at equal distances apart by means of distance pieces; the bars and distance pieces being connected together by passing transversely through them tie rods composed of ash or other hard wood. Screw threads are cut in the opposite ends of the rods; the threads at one end of the rods being designed to enter threaded holes in a side bar of the grid, and the threads at the other end, to receive wooden nuts, which, when screwed home, will bear against the other side bar, and hold all the parts of the grid firmly together.

APPLICATIONS FOR LETTERS PATENT.

EXTENSION OF THE WOOLWICH ARSENAL GAS-WORKS.—Considerable extensions of the scrubbing and purifying plant at the Woolwich Arsenal Gas-Works are about to be made; and the War Office has selected Messrs. Willey and Co., Gas Engineers, of Exeter, to execute the work.

TAUNTON GAS COMPANY.—At the forty-third annual general meeting of this Company to be held to-day, the Directors will recommend dividends of 8 and 7 per cent. on the two classes of shares. This will leave a balance of about £2112 to the good. The quantity of gas sent out in the twelve months ending June 30 last was 57,214,000 cubic feet.

MAITLAND GAS COMPANY, LIMITED.—The thirty-first half-yearly report of the Directors of this Company, a copy of which has been forwarded to us by the Secretary (Mr. C. E. Crutch), states that the profit on the working in the six months ending April 30 last amounted to £939 which was increased to £1018 by £79 brought forward. Out of this, a dividend at the rate of 8 per cent. per annum was recommended, absorbing £820; £300 was to be written off works; and the balance carried forward. The continued prosperity of the Company was reported; an impetus having been given to the consumption of gas by a reduction in price.

THE WOLVERHAMPTON CORPORATION AND THE WATER SUPPLY OF BILSTON.—At the last meeting of the Bilston Improvement Commissioners, a report by the Sub-Committee appointed to deal with the water question, as between the Commissioners and the Wolverhampton Corporation, was presented. It set forth the result of the recent proceedings in regard to the Provisional Order applied for by the Corporation, in which the opposition of the Commissioners failed, and stated that the Sub-Committee had decided not to proceed further in opposing the Order, because if the opposition were successful in the Lords—and there were good strong reasons for believing it would be—no benefit would accrue to the Commissioners if the Corporation withdrew, as they said they would, that part of the Order to which the Commissioners objected, beyond the barren result of compelling such withdrawal. The money which it would take to oppose in the Lords would go towards promoting a Bill to dissolve the contract. The Sub-Committee considered, therefore, that Parliament, on it being proved to them that the Commissioners could obtain a good supply of water for 2½d. per 1000 gallons, and that the Corporation proved in the arbitration that they could not supply it for less than 5d. per 1000 gallons, would, without hesitation, on the ground of public policy, determine the contract. The Commissioners were recommended to empower the Water Committee to seek an interview with the Local Government Board on the subject, and report thereon. This was agreed to.

THE ELECTRIC LIGHT QUESTION AT BATH.—At the meeting of the Bath Town Council last Tuesday, the debate on the report recommending the adoption of the electric light for the central part of the city, which was commenced at the previous meeting, was resumed. Alderman Clark pointed out that the prosperity of the city depended upon its attractiveness, and asked why they should not adopt the beautiful electric light, which was the "light of the future." Mr. Heywood expressed the opinion that the question should be deferred for at least twelve months; as the rates were already increasing, without a further addition being made to them by the adoption of the new light. Mr. Rubie considered they were a little premature, and thought they could afford to wait another year; but he should certainly like to see the light introduced at the baths. Mr. Cox argued that the electric light would cost the citizens £927 a year more than gas. A good deal had, he said, been made of the lighting at Taunton; but he was not quite sure that they might not hear of a catastrophe there. The Gas Company should improve their gas, and nothing more would be needed. Mr. Walker contended that the introduction of the electric light would commit the city to an unknown expense. Mr. Sturges, replying on the discussion, said "procrastination" was the "thief of time." Many a good purpose had been ruined by people being contented to think that something better would turn up, instead of striking the iron while it was hot—when they were able to make an impression. On a division, 22 voted for the adoption of the light, and 12 against—8 members (shareholders in the Gas Company) not voting.

Correspondence.

"AMBITIOUS" SECRETARIES.

SIR,—In a recent issue of the JOURNAL you very significantly applied the term "ambitious" to certain secretaries of gas companies; and much might be written on the subject which will apply equally well to ambitious engineers. It is much to be regretted, however, that anything should be said to stir up envy and jealousy amongst gentlemen occupying these respective positions. A secretary or engineer would be worth very little if he were not ambitious to promote the best interests of his employers; and there is not the slightest necessity for either position to be subordinate to the other. Neither gas engineers nor secretaries can exist without adequate support; and you may be very certain that the "self-sufficient committeemen and directors" would "belittle and ignore either one or both." There have been engineers who have simply been "ambitious" to serve their own interests, promote the use of their own patented machinery, buy materials in markets approved by themselves, fill the works with men of their own choosing, and the better positions with their own favourites or members of their own families. Can you wonder, therefore, that a secretary should endeavour to alter this state of things, and when such matters are brought to the knowledge of committeemen and directors, that they should support his efforts? On the other hand, there have been secretaries who have meddled to mar everything in connection with the gas-works. They have succeeded in setting committeemen or directors by the ears, and introducing amongst them personal bickering and strife. They have behaved harshly to their subordinates, and for themselves have laid up stores of "wrath against the day of wrath." They have thus brought about a state of things of extreme difficulty, and of constant irritation and vexation. There are, however, engineers and secretaries who do work well and happily together, without thought as to "who shall be greatest." Be it yours and mine to endeavour to extend and promote this desirable state of things.

The real difficulty to be contended against is that directors and committeemen too often overrule and ignore both the engineer and the secretary. They are apt to think that anybody can make gas and keep the accounts, and that £200 or £300 a year is a big salary. They are "practical" men themselves and see in a good bricklayer or a stalwart navvy all that is needed in a manager of works, and that there are plenty of clerks who have had a School-Board training who will fill the post of secretary at very low wages. There may be exceptional cases in which all this is true; but it ought to be remembered that the position of a gas manager, especially in the larger and progressive works, requires a man of engineering skill, chemical knowledge, general intelligence, and ability seldom (if ever) found in the merely so-called practical man. Nor will any clerk do for a secretary; and few there are who have the qualities you enumerate as fitting a man for this position. He must be "an educated accountant, with a knowledge of finance and some acquaintance with company law and practice." In addition, there are many qualities which he ought to possess, without which he will be utterly unfit for the position, or in it prove himself a fraud.

July 25, 1888.

RETORT.

THE PHOTOMETER QUESTION AT THE GAS INSTITUTE MEETING.

SIR,—The testings I mentioned in my letter in the JOURNAL for the 17th inst. are not those referred to by Mr. Heisch in his letter in your last issue, but a series taken at the Three Nuns Hotel, Aldgate, about a stone's throw from my office in Jewry Street. They were, I believe, made at the suggestion of the then proprietor, the late Mr. East, who complained that the gas supplied to his premises was not of the quality reported by the Examiner.

Mr. Dibdin says he is supported in his views regarding the Evans photometer by Mr. Heisch; but that gentleman states distinctly that he objects to it, because it gives *low results*—which is quite the reverse of what Mr. Dibdin advances as his reason for condemning it. Mr. Heisch attributes the low results to which he refers to the presence of an excessive amount of carbonic acid in the air supplying the burner. Now, a simple estimation of the quantity of carbonic acid in the air inside the photometer would settle this aspect of the question; and I am surprised that this has not yet been done. I have, however, commenced some experiments in this direction, the results of which I will forward to you in a few days.

I am afraid this subject cannot be satisfactorily discussed without introducing candles, which seems to be objectionable to Mr. Dibdin. Indeed, on reading his paper, the question immediately arises: How much of the blame hitherto attached to candles is fairly attributable to them, and how much to the photometer? For my part, I incline to the belief that the candles must bear most of the blame; but, in the absence of details showing the condition of the wicks, the position of the bend of the wicks in relation to the photometer-bar (in other words, the position of the candle-flames), the number of times the candles have been lighted and blown out before commencing the test, and the length of time they have been burning, it is impossible to criticize published results. My experience teaches me that fairly uniform results can only be obtained with candles under the following conditions:—(1) They should have been burnt until the tips of the wicks glow, blown out, and allowed to cool at least three times before use. (2) The tips of the wicks should be not more than $\frac{3}{8}$ inch from the top of the candle; and they should bend at right angles to the photometer-bar, so as to bring the flames in a line to the pointer. (3) They should never be allowed to burn more than 15, or less than 10 minutes before use. If these precautions are not observed, there is a risk of obtaining results higher than the truth, no matter whether an open or a closed photometer is used. I have a strong suspicion that the discordant results obtained by the several experienced Metropolitan Gas Examiners in July, 1879, before the Committee appointed by the Board of Trade to inquire into the question of standards of light, were caused by neglect of the first of the above conditions, as they were each supplied with fresh candles, and requested to use them as they were accustomed

to do. I was one of the Examiners, and my result was 16.3 candles; but I think others made the same gas 18 candles.

Having officially to test the gas at seven different provincial gas-works, I have, for many years, had to use a variety of photometers, including one of the "old converted" Evans (which is at the present moment in disgrace for giving low results). Whenever low results have been obtained, they have always been confirmed by the appearance of the flame; and when the results have been higher than the size of the flame would seem to justify, the candles have been found to be defective. Therefore I cannot support Mr. Dibdin in his condemnation of the Evans photometer.

If the Gas Referees, in their half-yearly "Notification," were to give as much attention to the mode of using the candles as they do to the extremely simple operation of estimating the sulphur in the liquor of the sulphur apparatus, and provide a stringent code of rules to be observed, I feel convinced that it would be found to be quite immaterial whether an open or a closed photometer was in use.

Poplar, E., July 27, 1888.

W. C. YOUNG, F.I.C., F.C.S., &c.

Since the above letter was in type, we have received the following communication:—

SIR,—I have completed my estimations of the amount of carbonic acid in the air inside and outside an improved Evans photometer; the results, stated in percentage by volume, being as follows:—

Inside Air, taken from immediately under the burner, gas and candles burning, and photometer closed—

(1) 0.0676 (2) 0.0601

Outside Air, taken from front of photometer, 5 feet above the floor or same height as burner in photometer—

(3) 0.0601 (4) 0.0563

Inside Air, taken from immediately under candles, 18 inches from the disc, photometer closed, gas and candles burning—

(5) 0.0563 (6) 0.0563

These experiments show very clearly indeed how efficient the ventilation is in this photometer, especially as each extended over two hours, during the whole of which period the photometer remained closed, whereas in ordinary use it is closed for ten minutes only. The higher results of Nos. 1 and 3 are sufficiently explained by the fact that they were taken at night, whilst the others were taken in the early part of the day.

In order that your readers may judge of the degree of purity the above figures indicate, I may quote as follows from the late Dr. R. Angus Smith's well-known work on "Air and Rain:—" "When people speak of good ventilation in dwelling-houses, they mean, without knowing it, air with less than 0.07 per cent. of carbonic acid."

Poplar, E., July 28, 1888.

W. C. YOUNG, F.I.C., F.C.S., &c.

MECHANICAL V. HAND STOKING AT THE MANCHESTER CORPORATION GAS-WORKS.

SIR,—In reply to Mr. West's letter in your issue of the 17th inst., I should like to add a few words, beyond which I do not desire to continue the correspondence.

I do not incline to enter on the further question raised by Mr. West as to the relative cost of hand and machine labour. My object was simply to correct Mr. West's error as to the cost of Nos. 1 and 2 retort-houses in carbonization. On referring to the wages book, I find that the total wages and the amount charged under each head as "Carbonization," &c., all bear the signature of "John West," as certifying to their accuracy. If there is any error, it is hardly for Mr. West to say so; but I believe them to be correct. The wages include sub-forgemen, firemen, machine-men, buttyers (i.e., men who open retort-lids, and assist at pipe-opening and wheeling coke from the house), scurfers (who also assist at pipe-opening), coal wheelers and quenchers, engine men, valve boys to work the "automatic" anti-dip valves, and extra men employed by Mr. West in winter for pipe opening and valve cleaning; all of which are classified by Mr. West under "Carbonization." There is an item of cost which is not included, which would have arisen under the head of "wheeling coal" had all the houses at the station been constructed like Nos. 1 and 2. In such case they would have had to share their proportion of the cost of wheeling coal to the breakers from the store accumulated during summer. As it was, the other two houses having, from their arrangement, to wheel all their coal, enabled Nos. 1 and 2 to take nearly the whole of their requirements from the daily supply, and the coal was consequently delivered direct to the breakers without the cost of wheeling.

That the figures which I gave as the carbonization wages were certified by Mr. West, is, I think, sufficient to justify my statements.

Manchester, July 26, 1888.

JOHN KING, jun.

MR. HUNT'S CRITICISMS ON MR. CARPENTER'S PAPER.

SIR,—I am rather disappointed with Mr. Hunt's response to my "questioning," as he puts it. I was afraid he would make a quibble about the adjective "workable," as very likely he considers there is no workable regenerative furnace except his own at Birmingham. So I will repeat the question, but leaving out the word "workable," and hope for an answer. I am glad to see that Mr. Hunt admits, although in a half-hearted kind of way, that it was London that set the fashion of regenerative firing in this country. This may be taken as "absolutely something" towards "the great advancement."

It is quite true I omitted all mention of the tar employed as fuel, because I had no means of knowing how much tar had been used in Birmingham. But I will take Mr. Hunt's figures, and grant the additional equivalent of 2.1 bushels of coke to the 9.9 bushels as per "Field's Analysis," giving the South Metropolitan Company, which he quotes, a full consumption of 12 bushels per ton on their make of 49.8, or about 25 per cent. At the same time there appears to be no reason why the make of coke per ton of coal should be less in Birmingham than at the South Metropolitan works. In fact, it ought to be larger, as in Birmingham much less canal is used—only 0.62 per cent. And, on looking down the list, I notice some of the neighbouring towns, using a very large quantity of canal (ranging from 12.30 to 50.30 per cent.), credit

themselves with a much higher yield of coke per ton; in one instance 51.2 bushels, or about 10 bushels more than Birmingham. But taking the make to be only the same as the South Metropolitan, 49.8 or 8.1 bushels to be added to the 9.6 bushels as per "Field," then the coke used for fuel in the furnaces at Birmingham is 17.7 bushels, or 35.5 per cent. of the make. This cannot be considered a very good record for such elaborately constructed furnaces; and I believe all, or nearly all, the furnaces in use in Birmingham are on the new system, while I think I am correct in stating that at the South Metropolitan works they have not more than one-fifth or one-sixth of their retorts heated with any description of regenerator furnaces. For some reason or other, I understand there is difficulty in applying them to the old retort-houses; but they are using them and erecting them in all their new houses.

But it is not so much with reference to the fuel comparison of the furnaces that I now write, although that is very interesting, and it is, of course, possible that there may be some cause for showing a low make of coke, which is not explained in "Field's Analysis." What I am disappointed in, and I think your readers will be also, is that Mr. Hunt declines to mention the places in the provinces where, as he states, "it is no uncommon thing to hear of a make of 10,000 feet and upwards per mouthpieces by regenerating furnaces." I should like to know where in England it is done; so, to take away any and all appearances of the "circular-of-inquiry" style from the question, and thus remove Mr. Hunt's objections, I will not ask him for the particulars I wished him to mention, but only for the names of a few towns where this make is obtained, and if it is done in Birmingham.

July 27, 1888.

A. B.

SIR,—In connection with the point raised by your correspondent "A. B.," will you allow me to state that, after deducting the fuel-value of the tar burnt, I sell 10.3 cwt. of coke for every ton of coal carbonized? Taking the figures given in "Field's Analysis" for 1887, Birmingham works out to 8.5 cwt. on the same basis; that is, it sells nearly 2 cwt. of coke less per ton of coal carbonized.

CHAS. C. CARPENTER.

July 28, 1888.

THE INCREASED USE OF COKE.

SIR,—My experience in the above matter, to which reference has lately been made in the JOURNAL, is a pretty wide one, having been for many years closely connected with new processes and new applications of fuel for manufacturing purposes; and there can be no doubt whatever that a very large proportion of the increase in the demand for coke is owing to the development of new processes and the improvement of old ones. I am daily brought into contact with manufacturers who are endeavouring to improve existing processes. In many cases gas is selected, but when the work to be done is on anything like a large scale, coke is practically the only fuel which is admissible for exact work; and a very few manufacturers in each town who commence using it will soon make a serious difference in the demand. Owing to its freedom of motion in a furnace, coke is the only fuel which can be employed in self-feeding furnaces; and these are the only furnaces of the slightest use for steady temperatures. Our system of using coke exclusively has been examined by visitors from all parts of the world, although there is nothing whatever in it except a little management.

As regards forced draught, this is quite unnecessary in any ordinary case. The mistake usually made is that the fire-bars are set much too low. Coke always requires to be used as a thick fire; and the top of it should be as near as possible to the boiler—a good average distance being about 12 inches from the top of the fire-bars to the lowest part of the boiler. Further than this, we fill up our boiler-flues with loose fire-brick, until the space does not exceed 5 inches. So that not only are the burnt gases kept close to their work, but we also get valuable radiant heat from the mass of bricks. The brickwork is loose, to admit of easy removal for inspecting the boiler. One point of importance for forge work is that the coke shall be broken to a uniform and small size.

Personally, I have no faith whatever in the domestic use of coke in open fireplaces. The constant liability to "sparking," and the consequent risk of fire, will always be a severe check on its use. On the Continent, where close stoves are universal, this objection does not exist; and therefore coke, being the best fuel for this class of stove, will always fetch its full fuel value. In England, where close stoves are comparatively few in number, this demand is, and will remain, very small; and it is to the use of coke for manufacturing purposes and steam raising, that we must look for a demand of any importance. If all were like ourselves, the coke question would never have been raised; as by a curious combination of circumstances, we not only employ gas and coke in fairly equal quantities, but we also use both tar and ammonia products; and our necessities therefore make us consumers of practically the whole of the residuals of coal carbonization. So far as the use of coke is concerned, I think I may fairly claim to have been directly the cause of a demand for many thousands of tons per annum for purposes to which this fuel has not been previously applied; and a large proportion of this demand has arisen within the last two or three years.

Warrington, July 26, 1888.

THOS. FLETCHER.

GAS-PIPES DAMAGED BY LIGHTNING.

SIR,—A singular occurrence took place at St. Ives (Hunts) on Wednesday last. A thunderstorm passed over the town, and the lightning struck the premises of Messrs. Cooto and Sons, coal merchants. Their spacious office is lighted by copper ventilating Argand gas-pendants; the products of combustion being conveyed through the ceiling into the roof. The electric current descended the ventilating shaft of the gas-burner over the desk of the cashier (who was fortunately absent at the time), and made its exit by the office door, which was open. No damage was done here. The adjoining house is occupied by one of the clerks; and there a gas-pipe was melted and the gas ignited. From an inspection made here, the electric current was conveyed into the roof of the dwelling-house by the spouting, which is coupled up by a zinc pipe to convey the rain water to a tank under the roof. A 3-inch lead pipe is brought from the tank down through a bed-room and into the scullery, and carried partly round the scullery near the ceiling; crossing at right angles, and so as to touch a 1-inch composition pipe which conveys gas to a bracket. Here the gas-pipe was fused, and the gas ignited. There

is no chimney in the scullery or in the bed-room above. No other damages to the premises could be traced. I shall be glad to learn whether any of your readers have had similar experiences.

Gas-Works, St. Ives, Hunts, July 28, 1888.

W. J. BEST.

Parliamentary Intelligence.

HOUSE OF LORDS.

MONDAY, JULY 23.

The Llanelly Local Board Bill was reported, with amendments. Petitions were presented against the Electric Lighting Order Confirmation Bill from the London Electric Supply Company, Limited, and from the United Vestry of the parishes of St. Margaret and St. John, Westminster.

TUESDAY, JULY 24.

The following Bills received the Royal Assent by Commission:—Gas Provisional Orders Bills (Nos. 1 and 2), Gas and Water Provisional Orders Bill, Local Government Board Provisional Orders Bill, Edinburgh and Leith Corporations' Gas Bill, Falkirk and District Water Bill, Frodsham Gas and Water Bill, Limsfield and Oxted Water Bill, Lincoln Corporation Bill, London Sea Water Supply Bill, and West Surrey Water Bill.

HOUSE OF COMMONS.

THURSDAY, JULY 26.

The Staffordshire Potteries Water Bill (Lords) was read the third time, and passed, with amendments.

FRIDAY, JULY 27.

PRIVATE BILL LEGISLATION.

Mr. CRAIG-SELLAR gave notice that early next session he would call attention to the report of the Joint Committee of the two Houses of Parliament on Private Bill Legislation [given in another column], and move a resolution urging the Government to legislate on the subject.

IRISH MUNICIPAL FUNDS AND LOCAL BILLS.

A Bill to enable Corporations in Ireland to apply municipal funds in the promotion of Local Bills in Parliament was presented and read the first time.

Legal Intelligence.

SUPREME COURT OF JUDICATURE—COURT OF APPEAL.

MONDAY, JULY 23.

(Before the MASTER of the ROLLS and Lords Justices LINDLEY and BOWEN.)

LEWIS AND OTHERS v. CORPORATION OF SWANSEA.—LEWIS v. THE SAME. PENALTIES FOR FAILING TO SUPPLY COMPENSATION WATER.

These were appeals from the decisions of Mr. Justice Denman, at Swansea, and Mr. Justice Wills at Cardiff, in actions brought by the plaintiffs to recover penalties and damages for not sending compensation water down a certain stream. The facts have already been reported in the JOURNAL.* The action in the first case was tried before Mr. Justice Mathew, who gave judgement for the plaintiffs; but the Corporation of Swansea obtained an order from the Court of Appeal for a new trial, which took place before Mr. Justice Denman, who did not accept the defendants' plea of inevitable accident, and allowed the plaintiffs penalties for four days—directing the damages sustained to be assessed. The plaintiffs entered a cross appeal, on the ground that the penalties ought to have been given for five days instead of four. In the second action Mr. Justice Wills gave penalties for 135 days, with damages, on account of the defendants having failed to supply water to the plaintiffs, who are mill-owners and riparian proprietors on a certain stream. The case for the Corporation was that there had been no failure, neglect, or default on their part, and that the omission to send down the water was owing to inevitable accident. The penalty provided in the Act of Parliament which authorized the Corporation to use the water in three streams for their water-works was £5 for every day they failed to send down the stream a certain quantity of water for the use of the riparian owners. Another question the Court had to decide was whether the penalty had to be paid to the owners as a class or to the owners separately; and the Corporation's case was that only one penalty of £5 was payable. Their main contention, however, was that they were not liable because the water had not failed through any act of theirs.

Mr. FINLAY, Q.C., M.P., Mr. R. T. REID, Q.C., and Mr. D. LEWIS appeared for the appellants; Mr. M'INTYRE, Q.C., Mr. HENN COLLINS, Q.C., and Mr. T. BULLEN for the respondents.

At the conclusion of the arguments,

The MASTER of the ROLLS proceeded to give judgment. He said that in order to entitle the plaintiffs to recover, it must be shown that the Corporation had neglected to do certain things, the failure to perform which prevented the flow of water down the streams. The reservoir had cracked; but this could not be regarded as an inevitable accident, seeing what was the extent of engineering skill in this country at the present day. The Corporation could have repaired the reservoir, and therefore it was an act of theirs which prevented the flow of water down two streams. Consequently they were liable. The question next arose, Who was to receive the penalties? The person only who brought the first action to recover a penalty could not recover it; a number of persons could not also recover for the same failure and neglect. It would be monstrous if more than one penalty could be recovered against the Corporation for one day's failure to supply water. The judgment of the Court would be that the plaintiffs who first brought the action for penalties should recover them. The penalties for the 135 days would be recoverable, and both the respondents would be entitled to such damages as they could show they had sustained. As the parties had partly succeeded and partly failed, there would be no order as to the costs of the appeal.

Lords Justices LINDLEY and BOWEN concurred.

Mr. FINLAY asked what order would be made as to costs of the trial before Mr. Justice Mathew. The plaintiffs, he said, had had their claim of £1000 cut down to £40.

Mr. M'INTYRE said the costs of that hearing were to abide the result.

The Court declined to make any order as to the costs of the trial before Mr. Justice Mathew.

HIGH COURT OF JUSTICE—QUEEN'S BENCH DIVISION.

TUESDAY, JULY 24.

(Before the LORD CHIEF JUSTICE and a Special Jury.)

BURSTAL v. HAWKSLEY.—A QUESTION OF COMMISSION.

This was an action brought by Mr. E. K. Burstal, the Water Engineer of the Oxford Corporation, against Mr. T. Hawksley, who had been specially employed by the Corporation in connection with the construction of the filter-beds for their water-works, to recover a share of the commission he had received on the work under an alleged agreement come to between them to share it in certain proportion. It appeared that in 1880 Mr. Hawksley, who had been Consulting Engineer to the Corporation of Oxford for upwards of 30 years, recommended Mr. Burstal as Resident Engineer, and he was employed as such at a salary. In 1880 the Corporation resolved to establish filtration water-works for the city; and Mr. Burstal, who had been associated with Mr. Hawksley at Rochdale and other places, drew some plans for the purpose (without, however, making any borings to ascertain the nature and capacity of the soil). The Corporation then consulted Mr. Hawksley, and in October, 1882, came to a resolution that the works should be carried out by him as the Consulting Engineer, and by Mr. Burstal as the Resident Engineer. In consequence, it was said, of some mistake, the word "jointly" was introduced into the minute of the resolution. But Mr. Hawksley pointed out that it conveyed a wrong idea; and the resolution really agreed to was that he should be employed as Engineer-in-Chief and Mr. Burstal as Resident Engineer. Mr. Hawksley, finding that Mr. Burstal had drawn some plans, desired to see them, but said he must be solely responsible for them, and that they must be drawn in his office. He made borings for the purpose of ascertaining the nature of the soil; and his plans were drawn with an important difference. The works occupied some years, and were not completed until 1886. In 1887, Mr. Hawksley received his commission—about £700; and Mr. Burstal claimed two-fifths of this sum, under the alleged agreement to share the commission in the proportion of two-fifths to three-fifths. This Mr. Hawksley entirely denied; and hence the present action to recover £284.

Mr. FINLAY, Q.C., M.P., and Mr. COURTENAY FOOKS were for the plaintiff; the ATTORNEY-GENERAL (Sir R. E. Webster, Q.C., M.P.) and Mr. DANCKWERTS for the defendant.

Mr. Galpin, who was Mayor of Oxford and Chairman of the Water Committee at the time the agreement was said to have been entered into, was called to prove a conversation respecting it.

Plaintiff also gave evidence as to the agreement. In cross-examination he admitted that, though he had been associated with Mr. Hawksley as local engineer in other water and sewage works, he had never before made such a claim upon him as the present. This he explained by saying that there had never been ground for such a claim. He admitted that Mr. Hawksley said he must make his own plans, and did so; and that he made borings for the purpose of ascertaining the fitness of the soil. He also admitted that the plan he had drawn would require an alteration or addition of a certain nature with reference to something in the character of the soil which he afterwards discovered.

This closed the plaintiff's case.

The ATTORNEY-GENERAL then addressed the jury on behalf of the defendant, whose position in his profession, he said, made it a matter of indifference to him whether he should pay £200 or £300, if it was really and legally due; but he felt it his duty to resist this claim, for which he considered there was no foundation whatever, and his yielding to which would set a very bad precedent as to the relations between resident engineers and engineers engaged, as he had been, upon special works. Mr. Hawksley had, he said, been employed to construct water-works in 130 places, in some of which Mr. Burstal had been Resident Engineer, and he had never had such a demand made upon him before; so that he felt bound to resist it on this occasion.

Mr. Hawksley was called, and entirely denied having had any conversation or made any agreement as to dividing with Mr. Burstal the commission he was to receive, which was the usual 5 per cent.; such a course being quite contrary to his principles and practice. He admitted that he received plans of the site, as well as the levels, from Mr. Burstal; but this, he said, was always the work of the local engineer. In no other way did he have any assistance from Mr. Burstal.

In cross-examination by Mr. FINLAY, witness said he could not remember having any conversation with Mr. Galpin on Oct. 5, 1882, as to a commission of 5 per cent. promised in a letter received by him from the Town Clerk on Sept. 11; his mind being quite blank as to what passed at that interview. Being referred to the resolution of Oct. 12, 1882, appointing himself and Mr. Burstal "jointly" at 5 per cent. commission, and that he was to have £50 a year, witness said that the latter arrangement was merely a general retainer, just as it might be in respect of a Counsel. He expected to be engaged when he first went down to Oxford in October, 1882; and then the whole matter went off, and the Corporation made a fresh engagement, reopening the matter on April 21, 1883. The commission of 5 per cent. was the usual commission paid to a chief engineer.

The LORD CHIEF JUSTICE: It was to be paid "jointly" to you and Mr. Burstal, as you very properly point out. Is that usual? Did you expect to get it all?

Witness: Certainly not, my Lord, as the resolution at that date stood. But I say the position has since been altered.

The LORD CHIEF JUSTICE: Then what is he to have out of it? You see, that is the question we are now trying.

Witness: I cannot say, my Lord, how much. I say that the original resolution went off. I said nothing to the original proposal—I was silent on the subject.

The LORD CHIEF JUSTICE remarked that there was an old saying that silence gave consent.

Re-examined by Mr. DANCKWERTS: When engineers are not appointed joint engineers, they do not share the commission. In the engineering profession "jointly" means that any responsibility entailed is to be shared jointly by both officers, in order to entitle them to share the commission; and in this case, on April 21, 1883, the Corporation passed a resolution specially refusing to allow Mr. Burstal to share any of the responsibility, and placing it all upon me. It is this that distinguishes the case. It is the universal custom that where there is an engineer-in-chief, he alone is responsible, and the resident engineer has no responsibility. At the meeting of the Water Committee on April 21, 1883, the matter of construction, &c., having been discussed, it was resolved that I was to be Chief Engineer and Mr. Burstal Resident Engineer. At that meeting I was, for the first time, instructed to prepare plans and drawings; I had done nothing in that way before. On that occasion Mr. Burstal stood up and said, "What is to be my position?" No answer was given. At this meeting every former arrangement was superseded, and an entirely fresh arrangement was entered into.

Mr. C. Hawksley said he had been in partnership with his father for 20 years, and was acquainted with the resolution in question. He agreed with what the last witness had said as to the professional custom. In his experience he had never heard of any such arrangement as that suggested

* See Vol. LI., pp. 735, 1096.

by the plaintiff. He first heard of it when the plaintiff's letter, demanding to be paid a share of the commission, was received.

Mr. W. J. Davey, secretary to the defendant, said he had frequently discussed and conversed with the plaintiff about the works, but before the receipt of the letter he had not heard a word about the alleged arrangement. In cross-examination, however, he admitted that after a conversation he had with Mr. Burstal at Oxford in October, 1886, the impression on his mind was that the plaintiff expected some present from Mr. Hawksley—not a share of the commission.

Mr. Bickerton, Town Clerk of Oxford, said at the meeting on Oct. 2, 1882, there was a discussion, and slips of paper conveying different ideas were handed round, and he gathered from these what the intention of the meeting was. Accordingly, before the resolution was put, he scratched out the words "as Consulting Engineer" after Mr. Hawksley's name, and "as Resident Engineer" after Mr. Burstal's, and substituted the word "jointly." At the next meeting it was resolved that the word "jointly" was not to constitute a partnership between Mr. Hawksley and Mr. Burstal, and that the former was to bear the sole responsibility. At a subsequent meeting, on April 21, 1883, there was this entry in the minute-book:—"The resolutions and correspondence as to the construction of the filter-beds were read, and, after talking the matter over with Mr. Hawksley and Mr. Burstal, it was resolved that Mr. Hawksley be Engineer-in-Chief and Mr. Burstal, Resident Engineer," &c.

In cross-examination by Mr. FINLAY, witness said by the resolution of Oct. 12, he should understand that the word "jointly" meant that Mr. Burstal would have a share in commission for extra work. Beyond this resolution nothing was ever afterwards arranged by the Corporation to pay Mr. Burstal anything for extra work. He did not understand that Mr. Burstal was to be paid by Mr. Hawksley. Asked who was to pay him, witness replied nobody, because the arrangement originally made that Mr. Burstal was to carry out the works had been abandoned; and though, no doubt, he had, in anticipation of being so employed, incurred some expenses, this did not entitle him to any extra remuneration. He had heard that Mr. Burstal expected to be paid something from Mr. Hawksley.

Mr. Downing, formerly Water Engineer to the city of Oxford and Mr. Burstal's predecessor in that office, said he had been Resident Engineer under Mr. Hawksley, and had never received or expected any commission. He always supplied the levels to Mr. Hawksley. He was now a member of the Water Committee; and knew nothing of any arrangement between Mr. Burstal and Mr. Hawksley as to commission. He knew of the resolutions of Sept. 7 and Oct. 12, and, in his opinion, by them Mr. Burstal was entitled to some remuneration; but he should say the proper persons to remunerate him were the Corporation of Oxford.

This concluded the defendant's case.

Mr. DANCHEWITS having addressed the jury,

Mr. FINLAY replied.

The LORD CHIEF JUSTICE then summed up. Having explained the nature of the claim and given the history of the case, he commented upon the various points in the evidence to which he considered the attention of the jury should be specially directed; remarking, in conclusion, that it would be for them to say whether Mr. Burstal had or had not satisfied them that the arrangement he alleged had been made.

The jury at once returned a verdict for the plaintiff for £284—the full amount claimed.

Judgment was given accordingly.

CITY OF LONDON COURT.—FRIDAY, JULY 27.

(Before Mr. Commissioner KERR.)

EAST LONDON WATER COMPANY v. FOREMAN.

To-day the above case, which was before the learned Commissioner on the 21st and 22nd ult., and raised the question of the liability of the actual consumer of water to pay the water-rates, again occupied his attention.

Mr. G. KEBBELL, the Company's Solicitor, stated that the action was brought to recover the water-rate due in respect of a supply given to a house in Mare Street, Hackney. When the case was before the Court on a previous occasion, the defendant contested his liability, and positively swore that he was not the occupier, but was only manager of the business carried on on the premises supplied. An adjournment was granted, to allow the owner, a Mr. Fortescue, to be made a co-defendant; but since then Mr. Fortescue had called upon him (Mr. Kebbell), and had shown him a lease by which the defendant not only became Mr. Fortescue's tenant, but covenanted to pay all rates and taxes.

HIS HONOUR asked if Foreman was in attendance.

Mr. KEBBELL said he believed not.

HIS HONOUR: He ought to be indicted for perjury. Meanwhile there will be judgment against him for the water-rate.

Mr. KEBBELL: I ask for costs on the higher scale, on the ground that the case involves a novel point, and is of public interest.

HIS HONOUR: No doubt it was a novel point, whether, under the circumstances previously stated, Foreman could be made liable; but the novelty arose from his lying.

Mr. KEBBELL: The section of the Act says that the person "requiring, receiving, or using" the water is liable to pay.

HIS HONOUR: Are you likely to get your money in this case?

Mr. KEBBELL: Not a farthing.

HIS HONOUR: Well, you ought to advise the Water Company to prosecute this man in the public interest. As to the costs, they will be allowed on the ordinary scale.

THE COST OF THE VYRWY WATER SCHEME.—The Water Committee of the Liverpool City Council have just issued their usual quarterly return of the expenditure upon the Vyrwy water scheme. It appears therefrom that, for the three months ending June 30, the sum spent amounted to £37,742 19s.; increasing the grand total to £1,769,843 19s. 2d. The details of expenditure are as follows:—Embankment and works in connection with the reservoir, £12,838 2s. 11d.; Llanwddyn quarries, £3556 4s.; aqueduct, £20,708; land and easements, £639 15s. 11d. The embankment and reservoir (now all but finished) have cost so far £496,204 4s.; the working of the quarries, £181,038 2s.; the aqueduct, including both pipe-line and filter-beds, £821,385 11s. 10d.; and land and easements, £271,216 1s. 4d. Of the outlay on the pipe-line, £437,585 9s. represents the cost of the iron pipes themselves. Of the cost of the embankment and reservoir, the amount set down to date for trials, preliminary works, Council and Committee expenses, and sundries, is £5417 7s. 9d.; the new church and vicarage at Llanwddyn and the removal of the graveyard have cost £7535 5s. 6d.; workmen's houses, hall, provision stores, stables, &c., £19,624; machinery, £21,753 12s. 3d.; miscellaneous plant, including waggons and carts, £16,331 1s. 3d.; horses, £9500 18s.; expenses of engineers, superintendents, clerks, draughtsmen, travelling and office expenses, £38,011 4s. 11d.; and general expenses (embracing maintenance of hospital, postages, jobbers, rain gauging, sundries, and petty cash), £9848 10s. 3d. In connection with the pipe-line, the expenses of engineers, superintendents, and clerks, and of 11 offices at different points of the line, come to £49,791 17s. 3d.

Miscellaneous News.

THE MANUFACTURE OF COAL GAS.

LECTURES AT THE CITY AND GUILDS OF LONDON INSTITUTE.

The third of the series of four lectures to students on "Gas Manufacture," was delivered at the City and Guilds of London Institute by Mr. LEWIS T. WRIGHT, Assoc. M. Inst. C.E., F.C.S., on Monday evening last week, and the final one on the following evening. Abstracts of the first two lectures appeared in the last number of the JOURNAL; and we now give summaries of the others.

In the third lecture Mr. Wright dealt further with the impurities contained in coal gas, and with the methods adopted for their removal; ammonia and its compounds being first referred to. He explained that theoretically there are two classes of compounds formed between the commoner acids which occur in gas and ammonia—one in which two volumes of ammonia combine with two of sulphuric acid or two of sulphuretted hydrogen; and the other in which complete saturation of the acids takes place, four volumes of ammonia combining with two of carbonic acid or sulphuretted hydrogen respectively. In employing ammonia as an agent for the removal of these objectionable acids, they would naturally prefer to use the combination which required least ammonia; but they could not always get what they liked, and, in practice, the engineer could not rely on 100 volumes of ammonia removing more than 50 volumes of carbonic acid and 12½ of sulphuretted hydrogen. Knowing the volume of ammonia in the crude gas, it was easy to calculate the amount of carbonic acid and sulphuretted hydrogen which could be removed by the ammonia in washing or scrubbing. To illustrate this point, the lecturer had drawn a diagram showing in an upright column varying quantities of ammonia per 100 cubic feet of gas, and on the base-line varying strengths of ammoniacal liquor; curves lying between the upright column and the base representing temperatures. From this it appeared, for example, that a gas standing over or in contact with a 5 per cent. ammoniacal liquor, at a temperature of 30° Fahr., would contain 30 grains of ammonia per 100 cubic feet; while if the temperature rose to 70° Fahr. the amount of ammonia would also rise to 70 grains. This showed the difference occurring in scrubbing during the summer months; but fortunately at that time there was less strain thrown on the scrubbing apparatus, owing to the smaller make of gas per diem. No apparatus, however, could yield results beyond those indicated on the diagram, which depended upon the tension of ammonia vapour over water at certain temperatures.

A large diagram was exhibited, showing the plant necessary for scrubbing; the capacity being 6½ cubic feet per 1000 cubic feet for use with gas liquor, and 8 cubic feet for use with clean water—assuming the liquor to be 3 per cent. In winter time the gas liquor would remove all the ammonia from the gas except about 25 grains per 100 cubic feet; and this could be dealt with by washing with clean water. The resultant strength of liquor would depend on two factors—the total quantity of ammonia in the gas, and the total quantity of water produced by the distillation of the coal; but to this must be added the clean water used in the final washing process. In cases where it was desirable to produce very strong liquor—for instance, where it had to be carried to a distance before being utilized—the quantity of washing water had to be reduced to a minimum. If a ton of coal produced on distillation 7 lbs. of ammonia and 15 gallons of water, and 2 gallons were used in the final washing, the strength of the liquor would be about 3½ per cent.—16-oz. liquor, or 8° Twaddell. Under such circumstances it would be impossible to turn out 5 per cent. liquor. In speaking of ammonia, he only meant that which existed in easily dissociated compounds, or "free" ammonia; not that which was commonly called "fixed," being combined with small quantities of sulphuric acid or hydrochloric acid, which would require some stronger alkali (such as soda, lime, or potash) for its separation.

Mr. Wright went on to remark that there were certain other compounds—cyanogen, &c.—in gas liquor, which had no practical interest to the gas maker; but the ammonia being removed, there were several technical impurities left, some of which were also legal impurities. There were still sulphuretted hydrogen and carbonic acid, and certain other sulphur compounds, mainly carbon disulphide, the amount of them varying with the description of the coal, and partly with the temperature of distillation. There were, however, certain limits. A normal amount of sulphuretted hydrogen per 100 cubic feet was 10 grains; and 12 grains of carbonic acid was also common in Newcastle coal. The other sulphur compounds varied largely with the coal used; some of the Silstone seams not yielding 22 grains of these compounds, while in other cases the quantity might reach as much as 80 grains. All these impurities could be removed almost entirely by treating the gas with moist lime, which would remove the whole of the sulphuretted hydrogen and carbonic acid, and reduce the other sulphur compounds from 40 to 12 or 15 grains; and in a number of small works this process alone was employed. But a more economical method had been found desirable in many cases. Lime had the property of forming sulphides with sulphuretted hydrogen; for instance—

This particular sulphide was very soluble. But this, together with another sulphide which was possibly formed, was easily destroyed by the action of carbonic acid, with the formation of the ordinary carbonate, and the re-expulsion of sulphuretted hydrogen; so that in the case of the purification of gas containing both sulphuretted hydrogen and carbonic acid, this action took place almost as soon as the sulphide was formed. Also, if it was necessary that no sulphuretted hydrogen should appear at the outlet of the purifiers, the quantity of lime used must be largely in excess of that which would be necessary for the removal of the carbonic acid only; and it was found more economical to remove the sulphuretted hydrogen by another agent—generally some hydrated form of ferric oxide. The lecturer then described in detail, with the aid of diagrams, the method of purification as carried on in a series of vessels, some containing lime, and others ferric oxide; and pointed out the desirability, in such a case, of thoroughly saturating the lime with carbonic acid, though practically, he said, the theoretical quantity of calcium carbonate could never be produced from moist slaked lime—there being a reverse action taking place which limited the principal reaction. He also pointed out that, in the removal of the other sulphur compounds, there was again liberated a certain amount of sulphuretted hydrogen, which had to be afterwards removed in another oxide purifier. This, therefore, was a comparatively complex system for effecting what could be done by the use of lime alone; but it was introduced for the sake of greater economy, and to avoid the inconvenience arising from having large quantities of foul lime to deal with. To completely saturate lime with carbonic acid, it was necessary to submit it to the action of 50 per cent. more gas than it could really purify; but the quantity of material to be used was largely determined by the mechanical assistance it offered to the passage of the gas. As a general rule, for every 100 tons of Newcastle coal carbonized per diem, each purifier should have an area of 360 square feet; and if it was fitted with four tiers of sieves, each having 7 or 8 inches of material, or (which was preferable) six tiers

with 5 inches, there would be in each purifier 33½ cubic yards. This was equal to 8½ tons of oxide of calcium, or 16½ yards of raw chalk lime, which doubled its volume when slaked, though some kinds of limestone would give three times their volume when slaked. This quantity of lime should absorb nearly ½ tons of carbonic acid; but, owing to the cause previously mentioned, its real efficiency was only 70 per cent. of what it would be theoretically. With these data, and knowing the quantity of carbonic acid there might be in any gas after the washing process, it was easy to calculate how much lime would be required for the removal of the carbonic acid. In 100 tons of a typical Newcastle coal, there would be 0·8 ton of carbonic acid; so that a purifier of the size he had mentioned, which had an actual efficiency of 4·54 tons of carbonic acid, would go on purifying gas for 5·7 days, and in so doing would also remove some portion of the troublesome carbon disulphide—probably about 10 grains per 100 cubic feet. In the scrubbing process also a small amount of carbon disulphide was removed—probably not more than 2 grains per 100 cubic feet.

Dealing next with the question of the use of ferric oxide, the lecturer pointed out that the difference between those forms which would, and those which would not react with sulphuretted hydrogen was so subtle as to elude chemical analysis; so that the value of any particular sample could only be determined by experiment. The most useful form was that known as bog ore, or natural oxide, which on its arrival at the gas-works generally contained 50 per cent. of water, 32 per cent. of ferric oxide, and 18 per cent. of vegetable fibre and other matters. Even of the ferric oxide, some portion would be inert, and probably not more than 22 per cent. was really active. It was therefore a rather dilute agent to deal with; and, in practice, it was necessary to use about 6 cubic yards of this material per 100 tons of coal—the exact quantity varying with the quality of the coal and other circumstances. When quite new, it was not very sensitive to the action of sulphuretted hydrogen, owing to the high percentage of moisture. It was in its best condition when the moisture was reduced to about 25 per cent.; but if much drier than this, it was dusty, and ran through the sieves. To prevent this it was often wetted; and this was sometimes carried too far. The stuff should be just damp enough not to pass through the sieves. After being saturated with gas in the purifying process, it would be found on removal to be black—in fact, to be no longer ferric oxide, but ferric sulphide; but, as the sulphur replaced the oxygen when in contact with sulphuretted hydrogen, so, if exposed to the air, the oxygen of the atmosphere replaced the sulphur, which was thrown out in the free state, and the material again became ferric oxide. Theoretically, this alternating process could be carried on indefinitely; but practically the limit was about 16 times. After this the free sulphur accumulated in the material, perhaps to the extent of 55 per cent.; and it then might become of value for the manufacture of sulphuric acid. The practical limit of efficiency was often reached long before 16 times—sometimes in four or five times. This might occur when the gas was led into the oxide purifiers direct from the scrubbers, or from the condensers, without having gone through a lime purifier.

In conclusion, Mr. Wright pointed out that there were many circumstances which might affect the choice of any particular method of purification. Where only lime was used, there would be a large quantity of spent lime produced; and where this proved to be a nuisance to the neighbourhood, the system might have to be abandoned. But the spent lime arising from the combined lime and oxide system was not inoffensive; it contained sulphur compounds, which, on oxidation by exposure to the air, liberated sulphuretted hydrogen and carbon disulphide. It was possible to ventilate these purifiers, or blow air through them, so that the lime when discharged should be free from offence; the oxidation being effected by the air sent through, which was afterwards purified in some suitable manner. Where this plan was adopted, however, precautions must be taken with regard to the temperature, which otherwise would rise so high as to destroy the apparatus. This was a matter that deserved careful attention, so as to avoid any possible complaint arising from the escape of sulphuretted hydrogen into the air.

In the concluding lecture, the composition of coal gas after the technical impurities had been removed was first dealt with. It was then, Mr. Wright remarked, a mixture of hydrogen, carbonic oxide, and certain hydrocarbons which were gaseous at ordinary temperatures—prominent amongst them being marsh gas, a small quantity of nitrogen, and certain hydrocarbons, which, if isolated, would not be gaseous at ordinary temperatures, but which existed in the gas in a state of vapour. The presence of oxygen in any quantity was evidence of atmospheric contamination; it not being produced by the distillation of coal. There were also some traces of sulphur, and minute traces of carbon, hydrogen, and oxygen compounds. Hydrocarbons were generally divided by chemists into two classes—those capable of absorption by fuming sulphuric acid or bromine, and those not capable of such absorption. Hydrocarbons of the latter class belonged to the paraffin series; and in ordinary gas analysis they were all put together under the head of "marsh gas," the first member of the series. Ordinary 16 or 17 candle gas, made from caking coal, would have something like the following composition:—

Hydrocarbons capable of absorption (the exact formula not known—C _n H _m)	Per Cent.
Paraffins (treated as marsh gas, CH ₄)	38
Carbonic oxide	6
Hydrogen	48 to 50
Nitrogen	2

The greatest interest, the lecturer remarked, centred round the first class; though the paraffins were also of some importance. A just conclusion as to the quality of a gas could not be obtained from its analysis, conducted in the usual way; for it might happen that a 16-candle gas would have a less proportion of absorbable hydrocarbons than that above shown, and, on the other hand, a gas having 6 or 7 per cent. of such hydrocarbons might not be of much higher luminosity. Until lately, it was usually supposed that the entire luminosity of the gas was due to these constituents; but this was not the case, for if they were all removed the remaining gas would have a luminosity of 7 or 8 candles. Assuming this to be the case, as it could not be derived from the hydrogen, nitrogen, or carbonic oxide, it must be due to the other hydrocarbons included under the name of "marsh gas." This gas itself, however, would not account for more than 2 candles; but it was practically impossible to distinguish in such an analysis between the paraffins themselves and mixtures of paraffins and hydrogens. This classification, therefore, was somewhat conventional; and the percentage of hydrogen was to some extent hypothetical. The exact quantitative analysis of coal gas was a matter requiring such great care and skill, that it was rarely attempted in gas-works; but it was interesting to know that there were other paraffins present besides marsh gas, because they might vary in amount in different coals, and this would help to explain why some gases containing a relatively small proportion of absorbable hydrocarbon had a very respectable illuminating power. The proportions of carbon and hydrogen in the first class of constituents—the C_nH_m—might be considered roughly as C₂H₆, though the figures varied somewhat with different samples. Amongst these hydrocarbons, the benzene series was included, and was of great

importance; and advantage was now being taken of this fact to obtain benzol from coal gas, which was, of course, thus deprived of the greater portion of its luminosity. This, however, was not an objection in the case of a colliery owner seeking to obtain by distillation all the valuable constituents of the coal; and a great deal of coal was now distilled, not to produce gas for lighting, but for its other products, tar, ammonia, and the valuable hydrocarbons—the residual gas being utilized simply as fuel. One of the hydrocarbons present, generally in very small quantity—naphthalene—was sometimes exceedingly troublesome, when the gas was saturated with it, because any lowering of temperature led to its deposition in a solid form, and thus to the choking up of the service-pipes, and sometimes even of the smaller mains. Naphthalene seemed to be born at a high temperature, and appeared amongst the decomposition products of many organic substances when submitted to great heats; and it was very prominent in some coals, such as those of Newcastle and South Yorkshire, which yielded on distillation thick tars and a considerable quantity of water. It seemed as if water vapour in the retort had some protective action on this hydrocarbon. Any coal could be distilled at such a low temperature that no naphthalene would appear; but when the heat was increased, this substance made itself manifest, and after certain temperatures were reached it increased more and more. The question of dealing with gas saturated with naphthalene was sometimes very difficult. If one could always ensure that the gas should be made and treated in the works at a lower temperature than it would ever be subjected to in its after-history, there would be no trouble; but it would often happen that gas was made during the hotter part of the day, and purified and dealt with at temperatures much higher than it was submitted to in the mains and services laid within a foot of the surface of the ground; those buried deeper than this undergoing no appreciable variation in temperature. The cure for this evil would consist in some method of artificially cooling the gas before it left the works. It did not necessarily follow that the gas was saturated with the vapour of naphthalene or any other hydrocarbon. Some portion of every hydrocarbon found in coal tar probably lasted, but to an extent depending in some measure on their vapour-tensions, at ordinary temperatures, and to a certain extent on the solvent power of tar on these vapours. There was a wide field of research open in the study of these various hydrocarbons, and their behaviour under different conditions.

The next subject referred to was the percentage of leakage, or unaccounted-for gas, due in great measure to the imperfection of the numerous joints, and practically varying directly with the pressure. It was pointed out that the difference between the quantity made, as measured at the works, and that sold, as arrived at by totalling the consumption at the consumers' meters, was not necessarily entirely due to leakage; the conditions of temperature and pressure not being the same. It had been calculated that a difference of 1½ per cent. was occasioned by such variations, which made the leakage appear so much larger than it really was. The cause of the luminosity of gas-flames was explained to be the incandescence of solid particles of carbon, raised to a high temperature by the combustion of the hydrogen. Thus the object to be aimed at was twofold—first, to ensure the presence of carbon capable of being raised to incandescence; secondly, a sufficiently high temperature. Modes of attaining the second object, by heating the air for combustion, were explained; and attention was then drawn to burners in which some extraneous substance was raised to a state of incandescence. One advantage in this case was, the lecturer said, that the light did not depend on the amount of carbon in the gas, but only on the temperature attained; and thus a gas of very low illuminating power might be made use of. Considerable developments of this principle might probably be looked for in the near future. The general habit of attributing all blackening of ceilings and walls to gas lighting was mistaken; for, wherever there were currents of air in a dust-laden atmosphere, the dust would be carried and deposited on obstructing surfaces. At the same time, there was no doubt that badly constructed burners occasioned smoke which might be avoided.

After referring very briefly to the different elements which had to be taken account of in calculating the cost of gas manufacture, the lecturer concluded with a few remarks on the utility of the jet photometer as a practical test of the illuminating power of gas.

THE COST OF THE OIL STREET LAMPS AT WINCHESTER.—From a letter recently written by the Town Clerk of Winchester to the lighting inspectors of York Town, it appears that the experience at Winchester for the past twelve years has been that at the contract price for the oil (namely "Royal Daylight" or "Tea Rose")—viz. 6½d. per gallon—the cost per lamp per annum is £2 5s. This includes the lighting, cleaning, and extinguishing, as well as repairs and renewals. The lamps are kept alight from an hour after sunset to an hour before sunrise.

THE LINCOLNSHIRE FEN WATER SCHEME.—The Engineer of the new Company which proposes to supply water in the Spalding, Deeping, Holbeach, and Sutton districts, has lately been making inquiries in the south of the county as to the reception of the Bill which has been before Parliament this session; and last Friday week the scheme was under discussion at the monthly meeting of the Long Sutton Local Board. All the members, except one, expressed themselves favourable to the scheme, and considered it desirable to encourage the Company in their project, since there is no water supply in the district, and in the case of a fire no facilities exist for extinguishing one. It was decided, after a long discussion, to hold a special meeting to further consider the question.

DISCOVERY OF A SURREPTITIOUS CONSUMPTION OF GAS AT BIRMINGHAM.—A few weeks since the inhabitants of Birmingham were startled by the announcement of the discovery of a surreptitious distillery in a railway arch; and hints were thrown out that others might be in existence. Further investigation has led to the unearthing of a larger and more important private still in the vaults underneath a house in Albert Street, Dale End; and, curiously enough, it has been found that it was being worked at exceptionally low cost, with fuel and light stolen from the Corporation gas-mains by an elaborate set of contrivances, so that the owners would be able to put the spirit in the market, if they chose, at a price that no honest distiller could compete with. The upper part of the premises is occupied by Messrs. Stephenson and Son, who are described as spirit merchants and general dealers; but both members of the firm have denied all knowledge of the stills. The cellars, they said, were rented by a man named Thompson, of whom they knew nothing, but who described himself as a cider merchant, and had paid six months' rent in advance. The Stephensons declared that they had never been in the cellars since they were let to Thompson, and they knew nothing of the means which had been adopted for lighting it and heating the stills with gas drawn from the Corporation pipes, some of it with piping 45 feet in length. Another part of the gas supply, used to light the upper and smaller cellar, appears to have been drawn from the pipe that supplied the meter in Messrs. Stephenson's own office, though the connection was severed at the time the examination was made. The offenders have not yet been discovered by the police.

MANCHESTER CORPORATION GAS SUPPLY.

REPORT OF THE GAS COMMITTEE FOR THE YEAR ENDING MARCH 31, 1888.

We have been favoured by Mr. Charles Nickson, the Superintendent of the Gas Department of the Manchester Corporation, with a copy of the report and statement of accounts of the Gas Committee for the year ending the 31st of March last. The Committee report as follows:—

The manufacture of gas, the condition of the works, and the efficiency of the department have been maintained; and the Committee have pleasure in giving the following particulars as to the year's working and revenue.

The quantity of coal and cannel carbonized was 293,348 tons, with an average production of 10,383 cubic feet of 19·96-candle gas. The use of improved carbonizing appliances has, during several years past, resulted in a steady increase in the yield of gas per ton, while the illuminating power of the gas has been well maintained. A considerable saving has been effected in the cost of coal and cannel.

The quantity of gas transmitted from the works was 3,45,727,000 cubic feet; being an increase of 0·85 per cent. over the previous year. The quantity of gas measured and accounted for was 2,897,933,000 cubic feet; leaving 147,794,000 cubic feet, or 4·85 per cent., of gas unaccounted for, owing to leakage and condensation, as compared with 6·34 per cent. last year. This result has been brought about by careful attention to the pressures, and the renewal of many old service-pipes.

The amount received for gas-rents, meter-rents, and stove-hire within the city was £277,464 8s. 3d.; and beyond the city, including public lamps, £103,775 5s. 8d.—a total of £381,239 13s. 11d., being an increase of £10,041 19s. 11d. over last year. The sales of coke, tar, and ammonia water amounted to £60,659 16s. 9d., or £2 8s. 4d. over the amount for last year. It is satisfactory to report that the prices at which recent contracts for tar have been let show a considerable increase on the prices which have been obtained during the past few years. The total cost of street lighting within the city was £29,471 18s. 2d., as compared with £28,955 8s. 9d. last year.

The result of the year's working, after writing off £33,623 0s. 9d. for depreciation, is a gross profit of £106,072 9s. 3d. After deducting therefrom the fixed charges for interest, £29,832 16s. 11d., street lighting, wages and repairs, £8528 19s. 4d., sinking fund, £26,454, and £23,331 paid to the city fund account during the year, there remains an amount of £17,925 13s., which has been transferred towards the liquidation of the adverse balance on profit and loss account in past years; thus reducing such balance from £45,857 7s. 3d. to £27,931 14s. 3d.

The question of depreciation has had the attention of the Committee for many years, and is still receiving their careful consideration.

Accompanying the Committee's report is the usual one by the Medical Officer of Health and Analyst (Mr. J. Leigh). He states that the average illuminating power of the gas during the year ended March 31 last was equal to 19·96 standard candles. With regard to its quality, the ammonia contained in it was less than 0·1 grain per 100 cubic feet; the carbonic acid, 2·9 feet per 100 cubic feet (being a little less than 3 per cent.); the sulphur, 37·34 grains per 100 cubic feet. Sulphuretted hydrogen was present to a slight extent on 18 days.

The accounts, audited by Messrs. Lees and Graham, follow the reports. Our usual extracts therefrom will be given next week.

THE TRANSFER OF THE EDINBURGH AND LEITH GAS-WORKS TO THE CORPORATIONS.

APPOINTMENT OF THE NEW GAS COMMISSION.

The Edinburgh and Leith Corporations' Gas Bill having received the Royal Assent last Tuesday [see our "Parliamentary Intelligence"], meetings of the Town Councils of both places were held on Thursday afternoon, to elect representatives on the Gas Commission to be constituted under the terms of the measure.

The Lord Provost (Sir T. Clark), presiding over the Edinburgh Council, said it was not necessary that all the members of the Gas Commission should be elected from the Council, but he presumed it would be their desire that on this, the first occasion, they should be all members of the municipal body. He had prepared a list which had only one defect—it nominated one name too many. He had put down all the members of the Gas Sub-Committee, and then he endeavoured to nominate members from the wards that were not represented upon that Committee. He would read the list, and if anyone would decline to act, the whole matter might be settled in that way; but, of course, this was merely a suggestion. He was a member *ex officio*; and the list he proposed was: Bailie Turnbull, Bailie Cranston, Bailie Roberts, Bailie Walcot, the Dean of Guild, Treasurer Boyd, and Messrs. J. C. Dunlop, M'Intosh, Colston, Younger, Robertson, and Pollard, all members of the Gas Sub-Committee, to whom he proposed to add Bailie M'Donald and Messrs. Drybrough, Kinloch Anderson, and Macdougald.

Mr. M'LACHLAN said it occurred to him that this was giving too much work, and it might be too much honour, to members of the Council who were Water Trustees. He thought those who were on the Water Trust should not be members of the Gas Commission. It was putting too much upon one set of men, and leaving the others outside. He moved that they take one member from each of the 13 wards of the city; and that, as far as possible, they should leave out members of the Water Trust.

Mr. BRYDEN seconded the motion.

Bailie RUSSELL considered it would be an advantage to have the same gentlemen on both Trusts, because they would then have only one set of people dealing with their streets.

Mr. SMITH CLARK said he should have been extremely glad if he could have given even a general support to Mr. M'Lachlan; but he confessed he could barely demur to his Lordship's proposal, because in the first set of Commissioners to be appointed there ought to be a preponderating representation of the Committee who promoted the purchase. He said so for the reason that upon that Committee and its leading members, would mainly lie, during the next few years, the responsibility of the purchase they had entered into—the blame if the purchase should turn out to have been an unfortunate one; the credit if it should be the other way. He would just make one other observation—that while the general majority of the Council should have a preponderating voice on the Commission, it would be of considerable benefit to the new body if the minority in the Council who disapproved of the purchase should also, to some extent be represented.

Mr. MACPHERSON was surprised that the Committee should desire to have the matter left entirely in their own hands. They were just the stage of promoters; and he thought that the gentlemen who had succeeded so far, should now be glad to be assisted by the critics of their former conduct. ("Hear, hear," from Mr. Smith Clark.)

The Lord DEAN OF GUILD (Sir J. GOWANS) was sorry to see the question of minority and majority brought forward. He thought they had buried that dagger in London; and he was surprised that Mr. Smith Clark should bring forward the idea of separation.

The Lord PROVOST thought the Dean of Guild had mistaken Mr. Smith

Clark's idea, which was to elect members of the minority in order to heal old sores.

Treasurer BOYD and Bailie TURNBULL both expressed their readiness to retire in favour of Mr. Smith Clark.

Mr. SMITH CLARK deprecated anyone retiring to let him in; and suggested that the matter should be put to the vote.

After a great deal of conversation, it was decided that those members who were present should hand in marked lists from which the votes could be counted. This was done; and the following was declared to be the result:—Mr. Colston, 28; Dean of Guild Gowans, 26; Mr. M'Intosh, 26; Mr. Pollard, 24; Mr. J. C. Dunlop, 24; Bailie Walcot, 23; Mr. C. Robertson, 23; Bailie Turnbull, 22; Mr. Macdonald, 21; Treasurer Boyd, 20; Mr. Smith Clark, 20; Bailie Roberts, 19; Mr. Kinloch Anderson, 19; Mr. Younger, 18; and Bailie Cranston, 16.

The Town Clerk intimated the meeting to be held next day in virtue of the Act, for the constitution of the Commissioners, the election of a Clerk, and the appointment of a Committee to meet with the Directors of each of the Gas Companies for the purpose of carrying out the details of the agreement.

At the meeting of the Leith Town Council, Bailie GARLAND, who presided, said they were to have seven representatives on the Commission, of whom one (the Provost) was an *ex officio* member. He thought that he himself, as Convener of the Lighting Committee, should also be a member; and he moved that the following be the Commissioners:—Bailie Archibald, Bailie Garland, Bailie Gosman, Treasurer Waldie, Mr. Fisher, and Mr. Robertson. Bailie Gosman declined to take office; and Bailie Scott was nominated instead. The gentlemen nominated were then elected. It was resolved to place on record the Council's high appreciation of the services of Mr. T. B. Laing, the Town Clerk, in connection with the purchase negotiations.

FIRST MEETING OF THE COMMISSION.

The first Meeting of the Edinburgh and Leith Gas Commissioners was held in the Council Chamber, Edinburgh, last Friday. On the motion of Treasurer Boyd, Bailie Turnbull took the chair, in the absence of the Lord Provost. Of the 23 Commissioners, 18 were present. The Town Clerk (Mr. W. Skinner) laid on the table a copy of the Corporations Gas Act, and read a minute of the Town Council meeting of the previous day, electing the Commissioners for Edinburgh, and an extract from the minute of the Leith Council intimating the election of their representatives to the Commission. He also read a telegram from Mr. Smith Clark regretting his inability to attend the meeting, but expressing his intention to take office. The Town Clerk then administered the statutory declarations to the Commissioners, after which each Commissioner signed a form of the declaration, which was to the effect that they would faithfully and impartially discharge the duties of the Commission to the best of their skill and judgment. On the motion of Bailie Turnbull, the Town Clerk was appointed Clerk to record the proceedings of the Commissioners until another Clerk should be appointed. The Town Clerk then asked the Commissioners to resolve whether their business was to be conducted in public or in private. Mr. Colston said there could be no doubt on this point. They were statutory Commissioners appointed for the public good; and he moved that all their business, with the exception of legal matters, be conducted in public. Bailie Turnbull seconded, and the motion was adopted. Bailie Turnbull called for nominations for the clerkship; intimating that the appointment would, in the meantime be an interim one. Bailie Archibald nominated Mr. James M. Jack, S.S.C., who was proposed for the clerkship of the Water Trust. Bailie Turnbull seconded. Mr. Kinloch Anderson suggested that the appointment should be delayed till the next meeting, when they would probably have a number of applications before them. After some conversation, it was decided to delay making an appointment till Monday; Mr. Skinner to act in the meantime. Mr. Colston then said that one of the first duties of the Commissioners would be to find money to pay away; and as the Commercial Bank had been the bank of the Edinburgh Gas Company, he proposed that it should be the bank of the Commission. This was agreed to. Replying to Bailie Archibald, Mr. Colston said that their first operation was to be an overdraft for £60,000. The Town Clerk next read a letter from Mr. Blair, W.S., in which the writer said the Commissioners would probably visit the Company's works on the 1st of August to formally take possession. Mr. Colston said it would be necessary to appoint three Committees. He proposed the following:—Works Committee: The Lord Provost, Bailie Roberts, Bailie Archibald, Bailie Walcot, the Dean of Guild, and Messrs. Colston, Robertson, Leith, Fisher, and Dunlop. Finance Committee: Bailie Turnbull, Treasurer Boyd, Provost Aitken, Treasurer Waldie, and Messrs. Pollard, Kinloch Anderson, and Macdougald. Law Committee: Bailie Cranston, Bailie Garland, Bailie Scott, and Messrs. M'Intosh, Smith Clark, and C. Robertson. This list was adopted, but it having been suggested that Mr. Waldie was acquainted with the coal trade, it was agreed to transfer him to the Works Committee, and to transfer Mr. Robertson to the Finance Committee. Mr. Pollard was added to the Law Committee to make the number an odd one; and, on Mr. Colston's suggestion, it was agreed that the Conveners should be members of all Committees. Provost Aitken was appointed Convener of the Finance Committee, and Mr. M'Intosh of the Law Committee. Bailie Walcot proposed that Mr. Colston be appointed Convener of the Works Committee, and this was agreed to. Mr. Colston, in acknowledging the compliment, said he might not go on for long, because he thought there ought to be a much more practical man in the position; but that during the progress of the negotiations he would be very pleased to act. Messrs. Colston, M'Intosh, Bailie Turnbull, Bailie Archibald, and Mr. Pollard were appointed a Committee to meet the Directors of the Companies on the 1st of August. The Town Clerk remarked that, at their next meeting, one of the duties of the Commissioners would be to fix the price of gas—whether they would adopt the Companies' price or alter it. Mr. Colston observed that it would be very foolish to alter the price. On the motion of Mr. Colston, it was remitted to the Law Committee to prepare a code of Standing Orders for the Commission, and to the Finance Committee to make financial arrangements for the transfer.

THE WATER SUPPLY OF LIVERSEDGE.—On Monday evening last week, at a meeting of the Liversedge Local Board, it was decided to ask the Bradford Corporation to receive a deputation for a friendly discussion on the question of water supply, with special reference to a proposal made by the Corporation to take over the Liversedge water undertaking, and distribute water to consumers in Liversedge on the same terms as the consumers in the borough. Strong opposition was raised by the proposal, it being the opinion of some members that the Corporation did not intend to serve the manufacturers of Liversedge on the same scale of charges as those within the borough, but would only do so by special contract; and it was upon this point chiefly that the interview was solicited.

LINCOLN CORPORATION GAS AND WATER SUPPLY.

THE WORKING IN THE PAST FINANCIAL YEAR.

The accounts of the Lincoln Corporation, in their capacity as the Urban Sanitary Authority, for the year ending March 25 last, have lately been issued by the Solicitor (Mr. E. P. Dalton), acting for the late Treasurer (Mr. T. G. Dale).

With regard to the gas undertaking, the capital account shows a total indebtedness of £191,340 2s. 3d.—viz., capital value of gas annuities, £171,450; loan on mortgage, £15,900; and balance advanced by bankers, £3990 2s. 3d. On the credit side, the cost of the undertaking is put down at £191,196 15s. 4d.; and the expenditure on new mains, services, and meters, £143 6s. 11d. The revenue account for the year gives a total of £36,813 18s. The cost of the manufacture of gas was £13,070 3s. 6d.—viz., coals, £8012 18s. 1d.; purifying, £642 0s. 7d.; salaries of officers at the works, £459 16s. 8d.; carbonizing wages, £2066 1s. 4d.; and repairs and maintenance of works and plant (including renewal of retorts, &c.), £1889 6s. 10d. A sum of £977 9s. 1d. was paid for the distribution of gas. Rents, rates, and taxes swallowed up £1013 11s. 3d. A sum of £836 17s. 8d. was expended in the purchase of gas cookers. For law costs £29 10s. 8d. was paid; and £35 5s. 9d. was awarded as compensations. The management expenses were £871 17s. 2d. Interest on loans required £305 16s. 4d.; and bank interest, £477 16s. 1d. The annuities paid amounted to £5071 9s. 5d.; and £1639 10s. 3d. was required to meet current liabilities—viz., for the proportion of interest on loans and annuities. There was transferred to the sinking fund a sum of £1647 3s. 5d.; and the balance was £10,837 7s. 5d. The credit side showed a balance from last year's account of £9562 0s. 7d. The sale of gas brought in £20,738 10s. 2d.—viz., £18,910 7s. 11d. for 141,828,000 cubic feet of gas supplied to consumers at 2s. 8d. per 1000 feet, and £1828 2s. 3d. for public lighting. The rental of meters yielded £1044 12s. 6d.; and of gas cookers £125 19s. 4d. For residual products a total of £4739 16s. 9d., was obtained—viz., £2746 1s. for coke and breeze, £866 1s. 4d. for tar, £1007 8s. 7d. for ammoniacal liquor, and £120 5s. 10d. for refuse lime. The sum of £576 11s. 7d. represents the value of gas cookers on hire and in stock, after allowing for depreciation at the rate of 20 per cent. The sinking fund account for the redemption of £185,795 17s. 10d. in 50 years, at 3 per cent., shows that since 1886 a total sum of £4966 3s. 9d. has been transferred from the revenue account, and that £77 12s. 2d. has been received as interest on the amount invested; making a total of £5043 15s. 11d. The general balance-sheet gives a total on the debit side of £205,420 3s. 3d., made up as follows:—Capital value of annuities, £171,450; loan on mortgage, £15,900; amount due to bankers, £351 2s. 5d.; sinking fund, £5043 15s. 11d.; balance at the credit of the revenue account, £10,837 7s. 5d.; proportion of interest on loan and annuities, £1639 10s. 3d.; and amounts owing for coal, £198 7s. 7d. The credit shows: Cost of works, £191,196 15s. 4d.; additions to works, £143 6s. 11d.; value of coals, tar, coke, and stores in hand, £495 18s. 6d.; value of cookers (after allowing 20 per cent. for depreciation), £576 11s. 7d.; book debts, £8934 4s. 3d.; Consols, £3368 6s. 8d.; and annuities redeemed, £705. There were 15,635 tons of common coal, and 97 tons of canal coal carbonized during the year. On March 25 there were 72,900 gallons of tar in stock, as against 86,720 gallons at the beginning of the year.

The revenue account of the water undertaking shows a satisfactory state of affairs. After providing for the expenses of working and interest on loans, there is an actual gain on the year of £502 10s. 2d. The water-rents yielded altogether £8530 3s. 11d.; £31 15s. 4d. was allowed by the bankers as interest; and £10 was received from the Corporation for rent of land—total, £8571 19s. 3d. The maintenance and working expenses amounted to £2177 12s. 3d.; the rents of reservoir, ballast-pits, &c., were £159 9s. 8d.; taxes and rates absorbed £558 12s. 5d.; and £24 0s. 11d. was needed for law costs. Interest on loans required a sum of £3326 1s. 11d.; and £1024 18s. 1d. represented the amount repaid on account of loans. These and two or three small items brought up the total expenditure to £8036 13s. 9d.; and at the end of the year a balance of £1633 19s. 6d. remained in the hands of the Treasurer, increased from £1098 14s. during the year. The capital account of the same undertaking shows that the purchase of the water-works originally cost £63,827, and that £42,608 8s. 2d. has since been expended in the purchase of land, the erection of new buildings, additions, and extensions. The gross amount of loans raised on the undertaking is £105,000, of which £10,378 5s. has been repaid by instalments; leaving a total of £94,621 15s. still owing. The general district rate account has also had a sum of £3200 repaid out of revenue.

THE DUBLIN CORPORATION AND ELECTRIC LIGHTING.

A Special Meeting of the Dublin Town Council was held on Friday, the 20th inst., to consider and take action on the letter of the Board of Trade, notifying that it is proposed to proceed to issue to the Corporation a Licence for electric lighting, subject to conditions as assented to by the representatives of the Corporation at the meeting at the office of the Board on the 3rd inst. These conditions were alluded to in the JOURNAL last week (p. 173). Mr. Robinson opened the proceedings by remarking that the business they had to discharge was of a purely formal nature. On the previous occasion, owing to the house being counted out, the letter of the Board of Trade could not be dealt with. He begged to move—"That the conditions contained in the letter of the Board of Trade, dated the 10th of July, be accepted, and that they be requested to issue the Licence in accordance with the conditions." Alderman Mulligan seconded the motion. Mr. Mayne said, in reference to the terms of the letter from the Board of Trade, an expression was used which might cause trouble in the future. They put in the condition that the works should be completed within 2½ years. These were not exactly the terms in which the representatives of the Corporation consented to this restriction; because, though the works might be completed so far as the lighting was concerned, if they wanted to extend, or do any more lighting that would involve the erection of additional plant, they would have to go to the Board of Trade again. He was sure this was not the intention of the Board of Trade in giving their decision. Mr. Dennehy said, although the Corporation had power to undertake electric lighting, there were difficulties in the way which it would be well for the Council to consider. If it turned out that they were losing £2000 a year by the electric lighting, each member would be personally liable for it; and they should also remember that what cost £16,000 to Mr. Mayne and his fellow-Directors of the late Electric Light Company was sold for £3000. Mr. Healy observed that Mr. Dennehy might make his mind perfectly at ease as regarded financial loss. Nearly every town in America was using the electric light, and it was employed in a great many towns in England; and everywhere it was a success, both as an illuminant and financially. There would be no rivalry between the electric light and gas, because gas would eventually be valuable for cooking and other purposes. Alderman Dillon suggested that steps should be taken to have the Licence extended so as to include private lighting. After some further remarks, Mr. Robinson moved the adoption of the following addition to the resolution:—"And so far as the completing of the installation at present contemplated, within 2½ years, the Council desires that the clause of the Licence should be so framed as to leave it open to the Council to make subsequently such further extension of this

system in the streets as from time to time they may consider advantageous." He said they had thought that by limiting their application to using the light for public purposes, it would meet with no opposition from the Gas Company. They considered that at least the Company would recognize the right of the Corporation to light their own streets; yet they had lodged a petition with the Board of Trade. Under these circumstances, they were not under any obligation to the Company; and Mr. Courtenay Boyle had stated that the taking of this Licence would not prevent the Corporation from applying next November for a Provisional Order for private lighting. The motion was agreed to.

THE MALVERN LINK GAS COMPANY AND THE LOCAL BOARD.

ADOPTION OF OIL FOR PUBLIC LIGHTING.

In the JOURNAL last week (p. 176) we announced that the Malvern Link Local Board had decided to light the roads in their district by oil-lamps during the coming winter; and that this decision had been come to as the result of a dispute with the local Gas Company. The dispute was not of the Company's seeking; and during its continuance they endeavoured to meet the views of the Local Authority, but in vain. It appears that early in April last, the Secretary of the Company (Mr. F. G. Underwood) wrote to the Clerk to the Local Board (Mr. G. H. Foster) submitting the following alternative terms for the public lighting:—" (1) The Company to supply the public lamps at 4s. 6d. per 1000 cubic feet; the quantity of gas consumed to be measured by meters fixed by the Local Board, say, at every fifth lamp; or (2) they will light the public lamps at such times as the Local Board may require, at a price to be fixed by arbitration in the usual way; or (3) if the Local Board is desirous of having the gas supply in its own control, the Directors will use their best endeavours to induce the shareholders to sell their undertaking to the Board on the like arbitration terms." To this the Clerk replied on June 8, to the effect that the Board were prepared to accept the offer of the Company to light the public lamps from Sept. 1, 1888, to April 30, 1889, at the price of 4s. 6d. per 1000 cubic feet, provided the Company agreed to allow the Board the discount, and adopt the terms and conditions set forth below, and provided also that the Company agreed to allow to private consumers in their district the discount mentioned. The terms and conditions above referred to were as follows:—" (1) That a discount of 6d. per 1000 cubic feet be allowed in respect of each account rendered by the Gas Company to the Board, provided such account be paid within a month after its delivery to the Clerk of the Board. (2) That the quantity of the gas consumed shall be measured by meters to be provided by and at the expense of the Local Board, and to be affixed to every tenth lamp; and the average amount of the indications of all such meters shall be deemed to be the amount consumed by each lamp. (3) That the indications of the meters shall be taken monthly jointly by a representative of the Board and a representative of the Company; and that in the intervals between such takings the meter shall be kept locked. (4) That each lamp shall be furnished at the expense of the Gas Company with a governor burner to be approved by the Board, and so constructed as to limit the consumption of the gas in each lamp to a quantity not exceeding 5 cubic feet per hour. (5) That the illuminating power and quality of the gas and the mode of testing the same shall be in accordance with the provisions of the Gas-Works Clauses Act, 1871. (6) That the lamps shall be lighted, extinguished, cleaned, and repaired at the expense of the Local Board. (7) That a discount of 6d. per 1000 cubic feet be allowed by the Gas Company to all the private consumers in their district who shall pay their account within a month after delivery thereof." The letter was laid before the Directors of the Company on the 10th inst.; and the reply sent thereto was that they did not see any reason to alter the terms of their previous letter. To this the Clerk of the Board rejoined that the Board were not prepared to alter or amend the terms of their letter, which they considered to be "fair and reasonable." There the matter ended; and the Board are now taking steps to light the district with oil.

DEVONPORT GAS COMPANY.

The Forty-fourth Annual Meeting of this Company was held last Tuesday—Mr. R. C. SMITH in the chair.

The report presented by the Directors showed that the gross revenue for the year ending the 31st of May was £23,022, as compared with £22,338 in the previous year; being an increase of £684, due exclusively to the increased sale of gas. Residuals, although slightly improved in price, had not, it was stated, recovered from the late serious depression. Sales of coke and breeze had realized £2803, and other residuals—tar and sulphate of ammonia—had produced £1420, as compared with £2492 derived from these products three years since. The total expenditure for coals, wages, materials, wear and tear, rent, rates, taxes, and other incidental expenses, amounted to £18,472, as compared with £17,976 in the preceding year; leaving a balance of £4549 to be carried to the net revenue account. After payment of the interim dividend authorized at the last meeting, there remained a balance of £5450, from which the Directors recommended dividends at the rate of 10 per cent. on the original and 6 per cent. on the guaranteed shares.

The CHAIRMAN, in moving the adoption of the report, congratulated the shareholders upon the revival of trade, not only in that part of the country, but throughout the kingdom. The Company had, he said, been in existence 40 years; and during the first half of that period, with the exception of the first five years, Devonport suffered from the paralysis consequent upon the diversion of its trade. It took 25 years to recover from the effects of that change; but that they had recovered from it in many respects was shown by the report presented that day. During the past year they had fixed 103 new services in the borough, which was about the average of the last ten years. During that period upwards of 1000 new houses had been built, and the builders found it to their advantage to have the gas laid on in the houses they built; for if they took the gas into the houses, they not only found purchasers more readily, but had a better class of tenants. As a rule, gas was laid on in all the new houses and this would account for the continually progressive increase in their supply, more particularly during the last ten years. No large structural works had been carried out last year, as had been the case in former years, when they were erecting new buildings and new holders, with the object of increasing their productive power and their storage. The past year was the first in which they had had the advantage of these increased appliances; and, though not quite up to their expectations, they were satisfactory in so far that they showed the Company was progressing, and he had no doubt would continue to progress in the future.

Mr. HONEY seconded the motion.

The CHAIRMAN having replied to several motions on the various items in the accounts,

The report was adopted, and the dividends recommended by the Directors were declared.

A vote of thanks was then passed to the Directors and officers, and the proceedings closed.

THE PROPOSED REFORM OF PRIVATE BILL LEGISLATION. THE PROCEEDINGS OF THE SELECT COMMITTEE.

In the JOURNAL last week (p. 155) we gave a summary of the report recently presented to Parliament by the Joint Committee of the two Houses appointed to examine into the present system of Private Bill Legislation. In view of the importance of this matter to a large number of our readers, it will be of interest to give the principal portions of the document. It may be stated, by way of introduction, that on the 12th of March last the House of Commons ordered the appointment of a Committee of six members to join a Committee of the Lords on the question; and a message was conveyed to the Upper House to this effect. On the 16th, a reply was returned that a Committee of Lords had been nominated. As finally constituted, the Committee consisted of the following members:—Earl Bathurst, Lord Monk Bretton, Lord Colville of Culross, Lord Balfour of Burley, Lord Kensington, Lord Stalbridge, Sir John Mowbray, Sir Joseph Pease, Mr. Raikes, Mr. J. Morley, Mr. Craig-Sellar, and Mr. T. M. Healy. The first meeting took place on Friday, April 20, when Lord Monk Bretton was appointed Chairman; and the Committee adjourned for a week. On the 27th it was decided that the proceedings should be open; and evidence was then taken. The sittings were generally held twice a week; and extended (with an interval at Whitsuntide) till July 12. The first witness was Mr. J. H. Warner, the Counsel to the Chairman of Committees of the House of Lords. Following him came the Counsel to the Speaker of the House of Commons, the Hon. Chandos Leigh, Q.C., and Sir Theodore Martin, K.C.B., President of the Society of Parliamentary Agents. The other witnesses (taken in the order in which they appeared before the Committee) were: Mr. J. Colquhoun, solicitor; Mr. R. Vary Campbell, Edinburgh; Mr. S. Pope, Q.C.; Mr. J. S. Beale; Mr. E. H. Pemher, Q.C.; Sir G. Rickards, K.C.B.; Lord Grimthorpe; Mr. Pembroke Stephens, Q.C.; Mr. A. Bonham-Carter; Mr. J. D. Marwick, LL.D., Town Clerk of Glasgow; Mr. J. Colston, Edinburgh; Rt. Hon. J. H. A. Macdonald, the Lord Advocate for Scotland; Mr. J. Beveridge, Town Clerk of Dublin; Dr. A. Bennett McGrigor; Sir W. Kaye, C.B., Q.C., Clerk of the Privy Council in Ireland; Mr. J. Gray; Mr. W. Hay, Town Clerk of Dundee; Mr. F. W. Pim, Dublin; Mr. J. McEvoy, Dublin; Mr. J. Berry, Aberdeen; Mr. J. Wilson, Greenock; Rt. Hon. E. Stanhope, M.P.; Mr. J. C. Bolton, M.P.; Mr. W. A. Ferguson Davie; Mr. J. F. Symons-Jeune; Mr. L. H. Courtney, M.P., Chairman of Committees of the House of Commons; Rt. Hon. Sir J. R. Mowbray, M.P., Chairman of the Committee of Selection of the House of Commons; the Duke of Buckingham and Chandos, Chairman of Committees of the House of Lords; Mr. W. Campion; and Mr. J. F. Rotton. On Thursday, July 12, two reports (one prepared by the Chairman and the other by Lord Balfour) were submitted to the Committee; the former being adopted with a few slight amendments, and ordered for presentation to both Houses of Parliament. This was done the same day. The following is the text of the principal portion of the report:—

The present system of Private Bill Legislation had its beginning in 1837, when the House of Lords determined to constitute the Committees on Private Bills of a small number of members having no interest in the measures submitted to them, and entrusted the nomination of such members to a Committee of Selection. The House of Commons adopted a similar procedure in regard to Railway Bills in 1844, but did not fully apply it to other opposed Bills till 1855. The establishment of these quasi-judicial Committees is admitted to have been a great improvement upon the former "open" or other large Committees, however composed, in which members having a local or personal interest, took part and voted. The system was further improved in the House of Commons by the creation in 1851 of a "Chairmen's Panel," a Standing Committee which supplies the Chairmen of all Committees on Railway and Canal Bills. Again, in 1882, the House of Commons, with the view of securing greater consistency between Bills dealing with police or sanitary matters, promoted by municipal and other local authorities, instituted a Standing Committee—the Police and Sanitary Committee—to which all such Bills have since been referred.

The establishment of the *Locus Standi* Court in 1865 tended to give greater harmony of action to the tribunals of the House of Commons, in some measure to abridge the labours of Committees, and perhaps to diminish the expenditure of suitors. Conflicting opinions have from the first been expressed as to the policy of maintaining this tribunal, but it is generally recognized that, to a considerable extent, it effects the first, and though in a less degree the second of the above objects.

The general supervision of Private Bills exercised by the Chairman of Committees in one House, and by the Chairman of Ways and Means in the other, and the Reports of Government Departments directing the attention of Committees to particular points in the Bills brought before them, contribute to maintain some community of action between these separate tribunals.

In further proof of the importance now attached to a tribunal of a stable character, it is to be noted that, with hardly an exception, every witness whose attention was directed to the point, whatever his view upon Private Bill Legislation in other respects, expressed or implied a preference for the Committees of the House of Lords, as composed of less fluctuating elements, and possessing a higher degree of quasi-judicial training and experience.

The resolutions of various public bodies in Scotland and of the Dublin Chamber of Commerce which have been brought before the Committee, condemn in strong terms the present system of Private Bill Legislation. The Committees of both Houses are, however, generally stated by witnesses to command confidence; and this view is expressed by several of those who wish to see them in whole or part superseded or supplemented by some other tribunal. On the other hand, it seems to be more or less reluctantly admitted, even by some of the supporters of the present system, that, whether owing to the greater demands of public and local business upon the time of members or to other causes, the Committees of the Lower House have of late years been less strongly manned than formerly. Several witnesses have referred to the circumstance that the character of Parliamentary Committees differs; and that their action and decision is uncertain, some viewing this as an objection, others as an advantage.

Irrespective of the merits or demerits of Committees, the centralization of all Private Bill inquiries in London is objected to, as attended with expense and inconvenience to suitors from a distance, by witnesses from Scotland and from Ireland. A central inquiry is also, in some cases, complained of on the ground of liability to error on the part of a tribunal which has not the opportunity of inspection on the spot. The feeling in favour of local inquiries for what are deemed to be essentially local questions, is intensified by national sentiment, and by a natural desire that the necessary expenditure should, as far as possible, be incurred in the locality interested.

The arguments for local inquiry are most strongly urged in regard to schemes concerning a particular community or district, such as various kinds of Municipal Bills, Bills for the alteration of boundaries, or for constructing or otherwise dealing with works affecting a strictly limited area. In regard to schemes of a more comprehensive scope and bearing, directly

or indirectly affecting an extensive area and widely-spread interests, such as many Railway Bills, and some large water supply and other schemes, it is not denied, or hardly denied, that a centralized inquiry is preferable, if not unavoidable. Even in such cases it is represented that Westminster should not necessarily and always be the centre selected; but that Edinburgh, Dublin, or some other centre might, according to circumstances, be more eligible. It is also contended that, in the case of an extensive undertaking, particular portions of it might, not unfrequently with advantage, be made the subject of a local investigation on behalf of, or a local inspection by the tribunal charged with the examination of the whole.

The expense incurred by promoters and opponents of schemes in Parliament is undoubtedly great. Many statements from Scotland and from Ireland have been laid before the Committee illustrating the actual cost of Private Bill Legislation, particularly of Municipal Legislation, and the items into which it may be resolved. It is asserted that it has the effect not only of preventing poor opponents from coming forward, but also of suppressing proposals for small undertakings.

Complaint has been made that the Borough Funds Act, 1872, does not apply to Ireland; and that Irish corporations are thus denied the facilities for promoting improvements possessed by other municipalities.

The principal causes of expense involved in the system of Private Legislation as at present conducted are alleged to be:—(a) The compression of the work of Committees of the two Houses not merely within the limits of a session, but in reality, owing to the intervals of time necessarily allowed between the stages of Bills, or other causes, within a part of a session. This congestion of business compels the engagement of several counsel, in the hope of securing the attendance of one. (b) The short daily sittings of Committees—especially of House of Commons Committees—added to the fact that Committees only sit five days in the week; and the uncertainty as to the day on which the hearing of a case will be commenced. These circumstances involve the detention of witnesses, depositions, and solicitors for a much greater number of days than would otherwise be required. (c) The liability of promoters to a repetition before a Committee of the second House of the contest they have encountered in the first, at the will of an opponent. (d) The cost of bringing up local witnesses, depositions, and agents, and keeping them in London. In regard to this item it is keenly disputed whether, if inquiries were held elsewhere, the expense would not be equalled or exceeded by the cost of conveying skilled witnesses and counsel to the locality, and many accounts and estimates, especially concerning Scotch municipal schemes, have been offered to your Committee by witnesses in support of their different contentions. Whether a local inquiry would or would not increase the expenditure upon the item in question in any particular case, seems to be a matter depending upon the nature of the scheme, and also in great measure on the discretion of promoters and opponents and their agents.

Suggestions for mitigating the evils complained of will be found in the evidence taken by the Committee, and more particularly in a paper presented by Mr. Warner, Counsel to the Chairman of Committees of the House of Lords; and in a memorandum submitted by the Society of Parliamentary Agents through their President, Sir Theodore Martin. The principal suggestions are: (a) The appointment of a Joint Standing Order Committee for both Houses, whereby one inquiry would in certain matters answer the purpose now served by two. (b) A reduction of the House fees imposed upon suitors. The annual sum of the fees of the two Houses has, on an average of the last ten or twelve years, amounted in round numbers to £58,000—viz., £28,000 for the Lords, and £30,000 for the Commons. At the same time, the expense of both Houses in relation to private business is variously estimated at from £16,000 to £20,000 a year. (c) A diminution of the number of Committees sitting simultaneously, by spreading their work over the session. No great room for improvement seems to be here afforded; and no effectual proposal has been made on the subject, except to put pressure on promoters and their agents. To do this to any purpose, certain amendments of the Standing Orders are pointed out as requisite. (d) Putting a check upon the repetition of a contest in the Second House, by requiring the opponent to show and to confine himself to special grounds on which he claims a re-hearing; at the same time enlarging the power of Committees to award costs, and perhaps requiring the opponent to give security for costs. (e) It has also been pointed out that the form of the notice to be given to parties affected by proposed schemes, and the number of advertisements thereof, required by the Standing Orders, might be curtailed, and a saving to promoters thus effected. It will be seen that these suggestions in no way tend to satisfy or allay the desire for local inquiries, and that they afford no scope, or hardly any, for economizing the time and labour of Members of the Legislature, especially of the House of Commons.

The number of Private Bills varies greatly from year to year, or in short cycles of years. The work of a year is not, however, to be altogether measured by the number of Bills, because it may happen that in any year a few important measures may give rise to protracted contests, and render its duties heavy. The last three years have been light years in contrast to the years 1882, 1883, 1884 immediately preceding them. The year 1887 was almost exceptionally light. In that year, 102 members of the House of Commons were employed upon Committees upon opposed Bills and Provisional Orders, which held in all 190 sittings; the average service of each member so employed amounting to less than eight days. On the other hand, it appears from Sir C. Forster's Annual Returns as to Private Bills, that in 1882 176 members were employed on such Committees, and the average service of each member amounted to 10 days. Without anticipating a recurrence (though that is by no means impossible) to the state of things which existed in 1865 and 1866—in each of which years more than 600 Bills were presented, of which 377 became law in one year, while in the other 392 Private Acts were passed, and 200 members of the House of Commons sat on Committees on opposed Private Bills—it is obvious that the mass or the weight of such business which Parliament on assembling at the commencement of any session may find awaiting it is a most uncertain element. Even the lightest years, and with the increasing disposition of the House of Lords to take a full share of the burden, it has now become most difficult to provide in the House of Commons for the discharge of the duties of Private Business Committees. If the House of Commons at its meeting in any year found itself confronted with an amount of private business approaching to that of some former years, or if the pressure of public business, or policy, induced it to add to the number of or to enlarge its Standing or other Public Committees, the private business of the Session might be brought to an absolute standstill. In such a case a large part of the Bills would have to be abandoned at a heavy sacrifice to the promoters and probable inconvenience to the public, or practically the entire burden must be thrown upon the House of Lords.

It remains, then, for consideration whether the time has not come when some more comprehensive reform of private business than any that has been adopted since the introduction of the present system of Committees in 1837 should be undertaken without delay. Broadly, three proposals have been put before the Committee. Each may be said to have been proposed and discussed on former occasions, but, submitted as they now are in altered circumstances and accompanied in many instances by

material modifications, they claim consideration. These proposals are as follows:—

(A) The establishment of Commissioners entrusted with the powers and functions of Private Bill Committees (and perhaps with some other duties in relation to private business) who should hold central or local inquiries according to the character of the scheme and the interests of suitors; the ultimate decision being always, in some form, reserved to Parliament. Various proposals for a Commission, fully and clearly set forth, will be found in the evidence of the Lord Advocate, Mr. Stanhope, Mr. Courtney, Mr. Pember, Q.C., and others. The plan described by the last-named witness was in the main embodied in a Bill introduced in a former Parliament by Mr. Craig-Sellar. General approval of, and a desire for inquiries not confined to Westminster, by some other tribunal than Parliamentary Committees, has been strongly expressed by a majority of the witnesses from Scotland, among others by Mr. Vary Campbell, Chairman of a Committee of Public Bodies, Municipal, Legal, and Commercial, 64 in number, extending over Scotland, and by Mr. E. Wilson, deputed to represent the Convention of the 79 Royal and Parliamentary Burghs of Scotland; by witnesses deputed to represent the Town Councils of Edinburgh, Glasgow, and of other Scotch cities; by Mr. Pim, delegated by the Dublin Chamber of Commerce, and in other evidence from Ireland. Objections to a Commission, more particularly to a permanent Commission, are stated in the evidence of the Duke of Buckingham and Chandos, Chairman of Committees of the House of Lords; Lord Grimthorpe; Mr. Warner; Mr. Chandos Leigh; Sir T. Martin, representing the Society of Parliamentary Agents; Mr. Beale, Solicitor to the Midland Company, and one of the Solicitors to the Railway Companies' Association, Mr. Pope, the senior practising Counsel at the Parliamentary Bar; Mr. J. C. Bolton, M.P., Chairman of the Caledonian and of the Callander and Oban Railway Companies; and some other witnesses.

(B) Joint Committees would, no doubt, effect a considerable saving of time and expense in the case of those Bills (apparently amounting on an average to one-fifth of the total number of opposed Bills in the year) that are made the subject of a second contest in the second House; but, like the minor suggestions for improvement of the present system they fail in any degree to meet the desire for local inquiry. Moreover, they would afford a less measure of relief to members of the House of Commons than is commonly supposed. That House would, no doubt, be called upon to supply only three, or perhaps only two, of its members to each Committee, instead of four as at present; but this gain would be in a degree neutralized by its being required to furnish members to more Committees—viz., to Committees on opposed Bills originating in the House of Lords, as well as on those introduced in the Commons. On the other hand, the House of Commons would have some compensation in not having, as at present, to man Committees on Bills sent down from the Lords and then opposed in the Lower House.

(C) Some witnesses have expressed themselves in favour of an extension of the system of Provisional Orders to all subjects of Private Bill Legislation, leaving it to the option of Promoters to proceed in any case by Provisional Order or by Private Bill, as they judge expedient. It seems to your Committee that this extension would, on the whole, be attended with advantage, especially if the opposition to Provisional Orders in Parliament were limited to one before a Joint Committee. Provisional Orders, having undergone one inquiry before coming to Parliament, might reasonably claim to be exempt from the ordeal of a threefold trial. The adoption of this plan would, however, afford only partial relief to Members of the House of Commons.

The Committee are then brought to the conclusion that, although a Commission must necessarily be an experiment, it presents the best hope of an adequate solution of the difficulties of the situation. The cost of a tribunal of a calibre to command confidence may, no doubt, be considerable; it being recognized as an essential condition of success that men of a high order of ability should be placed at its head. On the other hand, it must be remembered that the annual surplus (£40,000) of the fees imposed by Parliament on suitors over the expenses of the two Houses in connection with Private Bill Legislation, is such as to afford an ample margin for the cost of a Commission; and that suitors may fairly expect that, in return for the payments they are called upon to make, they should be supplied with the most efficient and convenient tribunal that the country can provide. The precise method of giving effect to such a change, and the amendments in law and in parliamentary procedure involved in the establishment of a Commission with the powers and functions contemplated, are matters which can best be determined and carried through by a Government with the machinery at its disposal and on its responsibility.

The Committee would, nevertheless, in closing their report, express the opinion that, of the different schemes laid before them, that submitted by Mr. Stanhope affords a ready basis on which to proceed, as combining a substantial accomplishment of the chief objects immediately aimed at with the least disturbance of existing interests and arrangements. In the event of such a scheme being adopted and of its operation proving satisfactory, it would admit at some future time, if it were thought fit, of being simplified and extended on the lines of the proposals that have been made by Mr. Courtney and others.

RISE OF WATER IN WELLS DURING RAINLESS SEASONS.]

A few weeks since our contemporary, *Nature*, published a letter from a correspondent who called attention to the (to him) mysterious fact that the water in two wells at Fareham rose several feet in the month of March, as he states, "after a continuance of north-easterly wind, without rain, but with half a gale blowing." Writing on the subject in a later issue of our contemporary, Mr. Baldwin Latham points out that the rise of water in the wells in question was nothing more than the ordinary rise due to percolation. For twelve years past, says Mr. Latham, I have been carrying on constant observations of the underground water-supplies in different parts of the country; and it is quite true that ordinarily the water in wells rises in the winter and falls in the summer. But this is by no means an exceptional rule; for in the present season there have been two low waters, the last of which occurred in the southern counties on the 8th of March in the present year. After that date commenced a very wet period; and before the end of the month over 2½ inches of rain had absolutely passed through the ground, as measured by my percolation gauges. The water in a well on the Surrey hills, which had been falling up to March 8, rose before the end of the month over 30 feet, which rise was entirely due to the replenishment from rainfall. I may point out that there are many wells at the present time in which the water is still rising, while in others in the same districts the water is falling. The simple reason for this is that, as a rule, underground water follows the same law as water flowing in a river—the floods or high waters descend from the highest to the lowest districts; so that at present in wells situated in high positions the water is falling, while the crest of the wave of high water in the same watershed has not yet been reached in the lower levels of the district. That the water in wells does fluctuate under certain conditions of the wind there is no doubt, as I have already drawn attention

both to the fluctuations which take place in the water-levels of wells under barometric pressure, and also in the volume of water discharged from the ground with a fall of the barometer. It should be noted that the rise of water in wells when due to barometric changes coincides with the fall of the barometer. Now a north-easterly wind as a rule is accompanied by a high barometer; and therefore is not likely to influence the rise of water in a well. During the month of March the rainfall was above the average, while there were comparatively few days with easterly winds—the only time when it could be termed a half-gale from the north-east occurring on the 19th of March, by which time the water in all the wells had made a considerable rise, simply due to ordinary percolation. Thus there is no mystery attaching to the rising of the water in these wells at Fareham. The rise simply took place from the replenishment of the springs, which this year occurred at a period somewhat different from ordinary years.

EDINBURGH CORPORATION WATER SUPPLY.

PROSPECTIVE EXTENSIONS OF THE WORKS.

It has become apparent that steps will require to be taken shortly to augment the water supply of Edinburgh, Leith, Portobello, and the adjoining districts. The existing works comprise the North and South Pentlands, which are estimated as giving between 7 and 8 million gallons of water per day. The supply from the North Pentlands is wholly spring water of the purest quality, and averages about 5 million gallons a day. From the South Pentlands—the Glencorse district—the Crawley main discharges 300 cubic feet per minute; being equal to about 2½ million gallons per day. With the exception of the Crawley spring, which averages about 75 cubic feet of water per minute, the remainder of the supply from this district is impounded water. Then there is the Moorfoot supply, which is estimated as capable of giving 9 million gallons per day. These works were authorized in the session of 1874; and the first supply from Gladhouse was turned on in June, 1879. Since that time the demand for water in Edinburgh, Leith, and Portobello has enormously increased, and in addition, Musselburgh, Dalkeith, Bonnyrigg, Roslin, Corstorphine, Juniper Green, and other places have been supplied by agreement; so that at present the quantity of water drawn from the Moorfoot sources is about 8 million gallons per day—showing a margin of only 1 million gallons per day. Should the demand for water continue at the same rate as for the last nine years, this supply would be used up in the course of rather more than a year; and as it requires at least five years to construct new works, it will be seen that the Water Trustees, who have to maintain, under penalties, a constant service in Edinburgh, Leith, and Portobello, have no time to lose in looking out for additional sources. In the former water controversy St. Mary's Loch was put forward as a source of inexhaustible supply. The Bill to sanction the works, after a severe contest, passed the Select Committee of the House of Commons in 1871, but was rejected by a Committee of the House of Lords, presided over by Lord Wharcliffe, on the ground that, with additional storage, for utilizing the water drawn from the then existing (Pentlands) source of supply, and with greater care and regulation as regards waste, Edinburgh could obtain all that was necessary for its wants. The rejection of the Bill was attributed at the time to the evidence of certain engineers, particularly Mr. T. Hawksley, who held that for £100,000 he could construct reservoirs in the Glencorse Valley, and that there was sufficient water to supply Edinburgh with 50 gallons per head per day. Up to this time, however, not a single extra gallon has been obtained from the Pentlands sources; and although the Trustees took powers, under their Act of 1874, to construct an additional reservoir at Glencorse for storing up the water that was alleged to run to waste, this reservoir has never been constructed. Looking to the future, the Trust has before it the Heriot, the Manor, and the Fala waters, as well as St. Mary's Loch, as sources of supply. The Heriot water was analyzed in 1869 by Dr. E. Frankland, and pronounced to be good. It lies near the Moorfoots, and was estimated as capable of supplying 9 million gallons per day; but it has always been felt that to touch the Heriot would raise such a storm of opposition from Galashiels and the landed proprietors, that the Trustees never ventured to face it. As to the Manor water, it is perhaps the finest water supply within the United Kingdom. Mr. Leslie, C.E., reported to the Trust in 1870 that it was capable of yielding about 13 million gallons per day for town supply, and that the water seemed to be pure and good. A suitable site for the reservoir was Posso, four miles from the junction of the Tweed. Mr. Leslie's estimate for the works at that time was £390,000. After the rejection of the St. Mary's Loch Bill in 1871, and the interdict upon the Trustees, a private Company, called the Midlothian Water Company, applied to Parliament in 1873, and obtained powers to construct works capable of yielding for the supply of the county—and for Edinburgh, should the Trustees choose to avail themselves of it—five million gallons of water per day. This scheme was somewhat different from Mr. Leslie's, as it only proposed to intercept the springs in the valley at the higher levels, so as to draw the water over the Tweed and Leadburn without tunnelling. In his evidence before Parliament regarding the water at that time, Dr. Frankland stated that the analyses showed both samples to be of excellent quality. They could not be surpassed in any respect for domestic purposes, and were palatable, clear, and soft, and probably there was no better water in the Kingdom. The Corporation of Edinburgh, in prosecution of the Moorfoot scheme in 1874, came into conflict with the Midlothian Water Company in regard to the supply of the outer districts; and eventually the Company was bought up for a sum of £10,000, which was given to them to pay their expenses. So that, as a matter of fact, the water supply of the Manor Valley and the property thereto, belongs to the Edinburgh Water Trust. A recent visit of the Trustees to this valley will no doubt bring out the fine quality of the water which the valley produces. There is scarcely any peat in the district, and the hills are bare, and really act as stores and filters for the water; moreover, it is essentially a valley of springs. As is well known, the quality of the water from the Moorfoots is decidedly peaty; and the fact that £10,000 has had to be expended at Alnwick Hill in the construction of filter-beds to make it fit for use, is the best proof that it is not of the finest description.

LEEDS WATER SUPPLY.—The Water Committee of the Leeds Corporation have lately inspected the work in process for the conveyance of water from the Eucup reservoir to the filter-beds. They found that operations were progressing in a satisfactory way—no untoward or unexpected difficulties have been experienced. For the new Blackmoor Tunnel a distance of more than 100 yards has now been excavated, at the Seven Arches end of the tunnel. The 42-inch mains, between the filter-beds and the old tunnel at the Seven Arches, will be laid in the course of a few weeks; after which the maximum carrying capacity of the old tunnel, of more than 15 million gallons per day, may be utilized. The average daily consumption of water in Leeds throughout the year is about 11 million gallons; but in exceptionally hot and dry weather the quantity used reaches 13 million gallons. Thus in a short time there will be available a daily supply of 2 or 3 million gallons more water than is required by the largest consumption so far recorded.

NOTES FROM SCOTLAND. (FROM OUR EDINBURGH CORRESPONDENT.)

EDINBURGH, Saturday.

This has been an eventful week in my neighbourhood. The great event which has so frequently cast its shadow over this page of the JOURNAL during the past two years has been at last accomplished; and before I see these "Notes" in type, the gas undertakings of Edinburgh and Leith will have passed into the hands of the Corporations. As your readers are aware, I have not hesitated to speak whenever I thought the Commissioners in charge of the negotiations were wrong; but now it is a pleasure to me to be able to place myself alongside them, and to record my satisfaction with the present position of affairs. The negotiations are past; and I homologate the terms agreed to—as why should not I, when the terms were what I had all along pressed the Commissioners to offer? Now I look to the Commissioners, when once they settle down to work, to conduct the gas supply in as enlightened a way as their predecessors have done. The Commissioners selected are able men; and every one must be pleased to see that the good sense of the Edinburgh Council prevailed over the rather narrow-minded policy of the Lord Provost. Mr. Smith Clark has obtained a place. His Lordship's list did not include Mr. Smith Clark; and, in fact, would have made the minority be represented on the Commission by their very weakest member. This is not the first occasion on which the Lord Provost has stood in the way of Mr. Smith Clark; for it is an open secret that but for him Mr. Smith Clark would have been on the Joint Committee from almost the very beginning. It was a mistake that he was not, because if he had been, a great deal of the speaking with which he occupied the time of the Council would have been expended in Committee. It is just possible, too, and even likely, that many of his objections would have been removed by reasoning in Committee; and in that way the negotiations might have proceeded much more harmoniously than they did. He has, however—thanks to the wisdom of the Councillors—gained a seat "among the prophets" at last; and it remains with himself to show whether he has any knowledge of gas manufacture and supply, or whether he has been trading upon an empty reputation. The Commissioners set to work in a thoroughly businesslike way, without bombastic utterance or self-glorification of any sort, for which they are much to be commended. They well know that they have much and exceedingly delicate work before them; and evidently until they are out of the wood, they are resolved to restrain their halloo. One of their first duties will be to appoint officers; and, in this, much tact will be required. They have already discussed one—the clerkship; and the appointment will be made on Monday of a gentleman who it may be expected will hold the office permanently. On that head I cannot help feeling that the Commissioners might have considered whether a better way than the appointment of a legally qualified Clerk would not have been to have appointed a Law Agent separately, and to have given the post to one of the existing officers of the Gas Companies. Both Companies were able to carry on under these conditions; and why should not the Commission? After the transfer is completed, the legal business cannot be much; and indeed point is added to my suggestion by the circumstance that whatever of directly legal business there may be to perform, will, even with a lawyer for Clerk, be performed by a separate Law Agent. Another reason why I think the Commissioners should not have gone outside their own office for a Clerk, is that there will undoubtedly be a plethora of *employés*, all of them trained to the work, for whom posts will have to be found, and some of whom, I fear, will, if not set to lower-class work, at least find their expectations of promotion barred by the appointment of outsiders over their heads. I would not have written thus but for a rumour that, in addition to the clerkship, the treasurer'ship is also to be given away to an outsider. There is but rumour on the subject, however; and I shall be heartily glad, for the sake of the Commissioners themselves, if it should turn out to be no more. Besides the Clerk and Treasurer, the Commissioners must have an Engineer, and likewise a Manager for both works. In these appointments they have material before them for much anxious deliberation; and it is to be sincerely hoped they will see their way to making the appointments on perfectly fair and just lines. In addition to these appointments, the Commissioners have before them the ticklish work of carrying through the transfer of the stocks—certainly a matter of detail, but one which will require their attention and close consideration.

The Commissioners had their first taste of work yesterday afternoon, and began to feel some of the difficulties which are likely to beset their path for some time, and make them realize that their position is not altogether a bed of roses. The Works Commissioners held their first meeting as soon as the public meeting was concluded, and indeed within half an hour of their appointment. There were submitted to them about 100 tenders for the supply of coal to the Edinburgh works of the Commission during the current year. The Committee felt themselves unable, without professional advice, to proceed with the consideration of the tenders; and the subject was deferred till Monday, when it is expected that the Engineer to one of the Gas Companies will be present to advise them.

Consequent on the transfer of the gas undertakings of Edinburgh and Leith to the Corporations, the Stock Exchange has made a change in the method of stating their quotation of the gas stocks. The Gas Act only received the Royal Assent on Tuesday; and on Wednesday the quotation appeared under the heading of "Gas" for the last time. Since then it has appeared under the heading of "Corporation and Municipal Stocks and Annuities." Formerly the price was quoted at so much per share of £25; it is now quoted at so much per £100—the Corporation annuities being calculated on this basis. To-day the quotation is £305 for £100 of the 10 per cent. stock, and £287 for £100 of the 9½ per cent. stock.

The Oban Police Commissioners, who are the lighting authority for the burgh, have had submitted to them by the Defries Safety Lamp and Oil Company a proposal to light and maintain the public lamps at much less cost than is paid at present. The Lighting Committee, like cautious Scotchmen, did not jump at the offer, but wisely sent a request that one or two of the Company's lamps should be lent for their inspection. On a subject such as this, the thought naturally arises that, if the Defries Company can confer such benefits on communities as they hold out here, they do not act with much public spirit in proposing to confer the benefit on such a small place as Oban. The cost of public lighting in Oban cannot be great. It is one of the worst-lighted of the small towns of Scotland I have ever been in; and as the charge for public lighting in such places as Edinburgh is very large, it is a pity that the Company cannot see their way to make an offer to light its streets "at much less cost" than is incurred for gas. Can there be any notion on the part of the Company of making the Oban scheme an advertisement, which, on account of the smallness of the town, would not be a costly one?

The works and plant of the Stromness Gas Company have been sold by auction for £800, to the Manager of the Company, on behalf, it is stated, of a new Company which is about to be formed.

The Edinburgh and District Water Trustees held a meeting to-day, at which the accounts of the Trust for the year to May 15 (a summary of

which was published in my "Notes" on the 3rd of July) were presented. Mr. Colston, in moving approval of the accounts, said it was satisfactory to know that there was a balance in the hands of the Treasurer of £7641; and, as to what they proposed to do with the money, he would let them know at a future meeting. They had spent £3000 more during the past year than in any former year on the renewal and distribution of pipes—the total spent being £4217, as against little over £1000 formerly. It was right also to state that, through the energy and zeal of Mr. Oliver, their interim Treasurer, they had £300 less poor-rates to pay than the previous year; and he also succeeded in getting the money in quicker and much more thoroughly than in any former year. Mr. Oliver was appointed Collector for the Trust.

(FROM OUR GLASGOW CORRESPONDENT.)

GLASGOW, Saturday.

Dr. Wallace, Gas Examiner for the city of Glasgow, has contributed a letter to one of to-day's papers on the question discussed on Thursday in Mr. Hislop's excellent paper read to the North British Association of Gas Managers. After admitting that Mr. Hislop had clearly established his position, Dr. Wallace goes on to say that, in regard to Glasgow gas, he is not permitted to use either the description of burner or the pressure of gas best suited to the quality of gas produced in the Glasgow Gas-Works. By the Act of 1860, it is clearly defined, he says, that the gas shall be tested by a union-jet, burning 5 cubic feet per hour at a pressure equal to a column of water 5-10ths of an inch in height. This was for gas of a minimum quality of 25 candles, and expected to average about 27 candles; and it was a suitable burner for gas of that quality. The Act of 1882 lowered the minimum illuminating power to 20 candles, but retained the burner formerly in use. In his evidence before the Parliamentary Committee, he clearly pointed out that the burner would not develop the full amount of light which the gas was capable of yielding; and that it would be necessary to manufacture gas which, tested by a burner adapted for that quality, would give about two candles more. He concludes by saying that, while his weekly returns show an illuminating power averaging 23 candles, the gas would, in any town not restricted in the choice of a burner and in regard to pressure, be stated to be of 25-candle power.

The most important event in connection with gas matters during the past week in this part of Scotland has been the annual meeting of the North British Association of Gas Managers; but next in importance to it is the announcement of a probable reduction in the price of gas in this city. A meeting of certain prominent members of the Corporation Gas Committee was held on Wednesday; and after the financial statement had been considered—which I referred to in last week's "Notes"—there was a sort of informal agreement resolved upon to recommend that a reduction in price of 2d. per 1000 cubic feet should take place; and that the recommendation should be submitted to the Gas Committee. This means that the price is to be reduced from 2s. 10d. to 2s. 8d. per 1000 feet. A meeting of the Committee was held on Thursday; but it was agreed to hold over, in the meantime, any formal resolution on the subject—partly, it is said, because of the announcement of the prospective reduction of price having got into one of the local papers without the matter having been brought up in an orderly way. There is every probability, however, that the proposed reduction in price will eventually be agreed to. In connection with this matter, I may mention that it has been agreed to recommend that depreciation on works should be written off at the rate of 5 rather than 7½ per cent., which was the rate fixed upon at the last balance; and that in addition the sum of £12,000 shall be written off the value of the Tradeston works, where important alterations and extensions are about to be undertaken. The net balance, together with the balance carried over a year ago, will make a sum of about £5000 to the good to enter the new financial year with. It is stated that the reduction in price is due in a great measure to the favourable terms on which the coal purchases have been made for the year 1888-9. There is also a very large expansion reported in the consumption of gas during the past year; no mean proportion of the consumption being due to the increased and increasing use of gas cooking and heating appliances, more especially during the summer and autumn months. The net balance in the accounts of the Gas-Stove, &c., Department is reported to be very favourable. This, it should be mentioned, is after making liberal allowances in various directions. This subject of the expected reduction in the price of gas has already excited considerable attention in many parts of Scotland—indeed, one of the Ayrshire newspapers of yesterday refers to the circumstance as an example which is commended to the Ayr Gas Company.

A Hawick newspaper of to-day is devoting attention to the subject of gas supply undertakings being in the hands of the corporations or special trusts; and quotes the instances of Edinburgh and Leith, where the works are just being transferred to a Gas Commission, and refers to the examples of Glasgow, Paisley, and Greenock. In these three cases the results, according to the writer, have been advantageous to the respective communities, by giving good and cheap gas to the inhabitants, while making handsome yearly profits, which have been applied for town improvements. The writer refers to the fact that a movement was made in the Hawick Town Council some years ago for the purpose of taking over the Hawick Gas Company's stock and works; the proposal, however, was not proceeded with, the Council not being generally in favour of it. Another arrangement was made between certain persons and the Gas Company, whereby the Company became bound not to divide more than 10 per cent. per annum, and to give the public the benefit of the surplus profit by reducing the price of the gas when it could be sold cheaper. This arrangement has worked very satisfactorily for the past 15 years; and the inclusion of representatives of the Town Council at the Gas Company's Board has done much to make the Hawick Gas-Works what they are—for, everything considered, this concern is as well managed as anything else of the kind in Scotland. The low price charged for gas in Hawick is sufficient proof of the works being well managed. It is affirmed by the writer, however, that the same advantages could all have been obtained, and a considerable annual surplus made and applied to the improvement of the town, if the whole gas concern had been bought up at the time the thing was first proposed in the Town Council. He goes on to show what might have been done in that direction, and illustrates his position by stating what Greenock and Paisley have done in the way of supplying cheap gas, and at the same time providing votes from the gas surpluses for various public improvements. But what is now reduced to a regular system in those two towns is not likely to become the rule in Glasgow—at least so long as the Corporation Gas Committee remains of the same description as that now in office.

The Scotch pig iron market has been animated this week, with a rapid advance in price during the last few days—up to 39s. 7d. per ton cash being reached by Scotch warrants. The outside public seem to be now more disposed to buy; and there is a better demand for iron all round.

There is an improving tone in the local coal trade; the business doing in the shipping department causing an air of briskness where formerly a dull state prevailed. Most of the collieries are busy with orders on hand; and these keep the workers in steady employment. Quotations are much harder than a few weeks ago; and in some instances small advances are being claimed outside the usual run of orders.

CURRENT SALES OF GAS PRODUCTS.

LIVERPOOL, July 28.

Sulphate of Ammonia.—The momentary quietness of the Continental demand seems to furnish dealers with an opportunity to attempt once more the promotion of a downward course. It will probably prove a fruitless effort, unless conditions more favourable to such a task are imported. Against the realization of this object is, first, the firmness of makers, who can calmly look on while their small stocks do not increase, and the make remains limited as at present; and second, the probability (not to say assurance) of large requirements during August, when those consumers who, disappointed by the firm prices, have been holding back, cannot delay their purchases any longer, independent of such orders as have been taken and have to be fulfilled by speculators. So even a temporary decline looks doubtful; and quotations are at any rate still well maintained. Parcels at Hull and Liverpool are especially scarce; and there is not too much offering at Leith. Some large enquiries have been in the market this week for Southern Ports and the Colonies. To-day the quotations are: £11 15s., Hull and Liverpool; £11 12s. 6d., Leith.

LONDON, July 28.

Tar Products.—The chief feature of the week has been the continued and improving demand for anthracene. Ninety per cent. benzole is also in fair request, and the price advanced 1s. per gallon. On the other hand, fifty per cent. is neglected at the old rates. Creosote oil stocks are low; and this article looks better than it has done for some time—chiefly owing to new uses for it. This is satisfactory to distillers, as the old time-honoured outlet for pickling timber is gradually but surely dying out before the steel sleeper, which the railway companies seem to prefer. Prices: Tar, 15s. to 20s. per ton. Benzol, 90 per cent., 2s. 10d. per gallon; 50 per cent., 2s. 4d. per gallon. Toluol, 1s. 8d. per gallon. Solvent naphtha, 1s. 2d. per gallon. Crude naphtha, 30 per cent., 1s. per gallon. Light oil, 3½d. per gallon. Creosote, 1½d. per gallon. Pitch, 12s. to 13s. 6d. per ton. Carbolic acid (crude), 3s. 5d. per gallon. Cresylic acid, 10d. per gallon. Tar salts, 15s. per ton. Anthracene, 30 per cent., "A" quality, 1s. 4d. per unit; "B" quality, 1s. 2d.

Ammonia Products.—Sulphate is decidedly firmer. The improved prices quoted last week have been fully maintained; and the make now being small, it is not unlikely that higher prices may be seen. Business during the week has averaged: Sulphate of ammonia, £11 12s. to £11 16s. 3d. per ton, less discount. Gas liquor (5° Twaddell), 8s. per ton, with a rise or fall of 1s. 6d. per degree. Liquor ammonia, 2d. per lb. Carbonate of ammonia, 3½d. per lb. Muriate of ammonia, brown, £18 per ton; white, £28. Sal ammoniac, £30 per ton.

[From the *Chemical Trade Journal*, July 28.]

Sulphate of Ammonia.—The sulphate market still keeps up its firm tone, though business is somewhat quieter than it was a week ago. Business has been done during the week at £11 15s., f.o.b. Hull; and some makers have refused this price, hoping to see values go still higher. The fact that so little is offering would, at first sight, seem ample argument for a further rise in prices; but when it is known that a "bull" movement is contemplated in certain quarters, makers should be certain that they are not aiding others to get rid of their purchases while they are left with considerable stocks. Beckett price is £11 15s.; while outside, London makes are fetching £11 16s. 3d. Leith and Liverpool values stand at £11 10s. to £11 12s. 6d., with a fairly active demand.

Tar Products.—Benzol prices retain their firmness noticed last week; and 2s. 6d. for 50/90's may be quoted as to-day's value, 90's remaining as last week. The demand for solvent naphtha is very good; and 1s. 2d. is about the price for 90 per cent., distilling at 160° C. Still the demand for creosote keeps increasing, mainly for use in the Lucigen; and tar distillers will do well to make themselves acquainted with the exact qualities required for the different lamps. Crude carbolic remains *in statu quo*; while business has been done in anthracene at slightly improved prices over those of last week. Pitch sales have been made at 12s. 6d. to 13s.—probably the latter price is the more correct for normal business.

DARWEN CORPORATION GAS AND WATER STATISTICS.—The Darwen Borough Treasurer (Mr. J. H. Elleston) has just issued his abstracts of the Corporation accounts for the past financial year. Those relating to the gas undertaking show that the sale of gas realized £16,595 2s., the rent of meters was £136 13s., and residual products returned £1844 18s.; making a total of £18,829 8s. The manufacture of gas has cost £8254 4s.; and its distribution—viz., inspectors, repairs and maintenance of pipes, public lamps, &c., £779 11s. There is an item of £371 9s. for management; and rents, rates, and taxes reached £1189 6s.—making a total of £1059 11s. There is a balance of £8188 13s. carried forward. There were 752,000 cubic feet of gas purchased from the Blackburn Corporation during the year. The net profit was £1768 9s. The capital account shows that during the year £12,087 10s. was expended in the erection of new works. The Blackburn gas purchase mortgages sinking fund account shows a balance of £338 6s. The water-works revenue accounts show:—Receipts, £6850 2s.; expenditure, £6850 2s. There was a balance against the water-works last year of £2907 14s.; but this has now been extinguished by the amount being appropriated from the gas profits. The balance on the water-works sinking fund account is £3402 4s.; and on the water annuities sinking fund account, £4077 14s.

THE CONVEYANCE OF THE VYRNWY WATER TO LIVERPOOL.—At the Surveyors' Institution, Westminster, last Thursday, the inquiry instituted by the Board of Trade to determine whether the pipes in connection with the Vyrnwy scheme of the Liverpool Corporation should be carried underneath the River Weaver in a tunnel, walled passage, or culvert, or be placed in the bed of the river (see *ante*, p. 176), was resumed before Sir Douglas Galton. The Corporation were again represented by Mr. Pember, Q.C.; and the Weaver Trustees by Mr. Higgin, Q.C. Among the witnesses called were Mr. Lionel B. Wells, Consulting Engineer to the Weaver Trust, and Mr. Leader Williams, Engineer of the Manchester Ship Canal. The former gentleman considered that to lay steel pipes in a trench in the bed of the river, as proposed by the Corporation Engineer (Mr. G. F. Deacon) would be a constant source of danger to navigation, would be less economical than a tunnel such as he suggested, and was not the best mode that could be adopted. Mr. Williams would not go so far as to say it would be impossible for Mr. Deacon to float large flexible steel pipes across an important navigation, but it was an experiment he had never known to be tried. He thought it would result in delay to the trade during construction, and when it was completed would be a work not satisfactory either to the Corporation or to the Weaver Trustees. The only way to his mind would be to adopt a cut-and-cover arrangement, so that an examination internally and externally might take place periodically. By this arrangement he was satisfied that the work might be efficiently done for £4000, without any undue risk to the navigation, and with absolute safety to the water-pipes after they had been put in. Speeches by Counsel closed the proceedings; and Sir Douglas Galton will present his report in due course.

THE DANGERS OF ELECTRIC LIGHT INSTALLATIONS IN THUNDERSTORMS.—The residence of Sir Albert Sassoon, in Eastern Terrace, Hove, narrowly escaped destruction by fire on the night of Sunday, the 22nd inst. During the heavy thunderstorm which occurred that night, one of the maids, who had been roused by the storm, was startled by a smell of fire coming from the entrance hall, which is lighted by incandescent electric lamps. The girl called the butler, who found that flames were flickering near one of the lamps. He poured some water upon the spot; and in this way the outbreak was checked. One of the lamps was broken, and the woodwork near it scorched. It is supposed that the wire was struck by lightning, which was thus conducted into the house.

LANCASHIRE WATER SUPPLIES.—The heavy rain which has fallen recently has largely increased the stock of water in the reservoirs of the Lancashire towns, which suffered most severely from the effects of the drought. In Liverpool, the latest report is that the stock of water in Rivington Reservoir has increased by 223 million gallons during the past fortnight. The restriction of the supply to six hours a day is, however, maintained; the stock being still 940 million gallons below that of the same period last year. At Bolton the full supply of water was resumed last Wednesday. The restriction dated from the 20th of June, when there were 304 million gallons in store, against 620 millions at present. The Darwen Corporation have also found their reservoirs replenished; and it is estimated that the supply will last throughout the summer, independently of the purchases from the Blackburn Corporation.

CAMBRIDGE GAS COMPANY.—The half-yearly general meeting of this Company was held last Friday—the Rev. Dr. Phelps in the chair. In their report, the Directors recommended a dividend at the rate of 10 per cent. per annum on the original consolidated stock, and at 7 per cent. per annum on the consolidated stocks of 1880, 1882, and 1885, and on the new £10 shares. This was agreed to. The report of the Manager (Mr. J. Weeks) showed that the whole of the works are in good repair, and that the increase in the consumption of gas during the half year ending June 30, had been equal to the average increase of former periods; while the illuminating power, pressure, and purity of the gas had been maintained. The report was adopted. The retiring Directors (Dr. Phelps and Mr. C. Balls) and the Auditor (Mr. G. W. Fitch) were unanimously re-elected, and a vote of thanks to the Chairman closed the proceedings.

THE NORTHERN COAL TRADE.—There has been a slight fall in the demand for steam coal in the North; but it is believed to be temporary only, and it still leaves most of the chief collieries well employed. The price varies a little more—from 7s. 6d. to 7s. 9d., less a slight discount at times, and with a proportionate price for second qualities. Gas coal sells much more freely just now, not only on old contracts, but there is a larger shipment; and the inland gas companies are beginning to feel the increased consumption of gas through the lengthening of the nights. In the course of a few weeks much larger quantities will be sent to the greater companies; but it is already evident that the range of the freights for carriage by sea will be higher than last year. Household coal is only slow of sale. But manufacturing coal is more in demand; and, with the greater trading activity, there is the expectation of higher prices for this class of coal. Gas coke is in demand, and is now very scarce.

THE LEAKAGE OF THE HEYWOOD RESERVOIR.—During last week a large staff of workmen was employed, under the immediate direction of Mr. J. Diggle, the Engineer, opening down to the coal workings under the east embankment of the new reservoir at Clay Lane. Portions of the workings have been bored; and, as was expected, the recent leakage is entirely attributable to the end of the workings not having been sufficiently packed with rubble stone as ordered by the Engineer when the embankment was in course of construction. It is expected that the expense of making good the defect will not be great; but, to prevent any mishap, the Engineer has directed investigations to be made in other portions of the workings beyond those points where the leakage actually occurred, with a view of ascertaining beyond doubt whether there are any other defects in the stone packing. This will necessarily occupy some time, as the operations can only be proceeded with slowly. There is no settlement whatever in any portion of the embankment, and, so far, the Engineer has not any reason to fear that serious damage has been done to any portion of the embankment by reason of the recent leakage.

SKIPTON WATER SUPPLY.—About a month ago, the Skipton Local Board received the report of the Engineer (Mr. Hill) who had been engaged to investigate the subject of an increased supply of water to the town, and since then several discussions on the schemes recommended have taken place at the Board meetings. The report contained three suggestions for the augmentation of the supply—the first, to take additional drainage-ground to the east of the existing works, which would provide a supply for 10 or 14 years, the cost, exclusive of the land, being estimated at £5000; the second, to extend the present works into the Cowder district, the water from which should be conveyed to the Winny Gill reservoir, which would last 12 or 13 years, and would cost £5700 exclusive of land; and the third and most important, to construct a reservoir at High Skibeden, to contain 80 million gallons, with a drainage-area of 295 acres, capable of supplying 380,000 gallons per day, the cost being set down at £14,500. At a meeting last Friday week, the Chairman (Mr. J. B. Dewhurst) moved that the Board adopt the last-mentioned scheme, which had been recommended by the Water Committee. An amendment in favour of carrying out the Cowder scheme, but at a cost of £2000 only, was moved by Mr. J. Hogg; and this was carried.

THE NEW WATER-WORKS OF THE SOUTHAMPTON CORPORATION.—The Southampton Town Council, at their meeting last Wednesday, had a long discussion on a communication received from the Water Engineer (Mr. W. Matthews, Assoc. M. Inst. C.E.) relative to the work of driving the headings at Otterbourne, in connection with the new water-works. It appeared that Mr. Matthews had, at his own expense, caused an additional length of heading to be driven for his special information and guidance, and this fact he admitted he had kept from the Council. He submitted, as an explanation of his conduct, that a heavy physical and mental strain had been imposed upon him in carrying out the new works; and this had been terribly augmented by the uncharitable comments of a section of the outside public. The new works had, he said, been pointed out as a complete failure; and he had been held up to contempt and ridicule by those whom he had no chance of answering. The effect had been to greatly upset his mind; and in over-anxiety to strengthen himself with additional information, and thus protect, as he thought, his reputation and judgment, he privately carried on the heading, with the view of ascertaining beyond doubt the best course to advise the Council to pursue in seeking an augmentation of the available water supply. Of the ultimate success, neither he nor the many engineers of repute who had visited the works had ever felt a doubt, though he admitted that in a similar case he should not again adopt the same type of wells. He asked the Council to accept his apologies and regrets; and expressed the hope that he might by his future conduct and energies in their service regain that measure of confidence which he could not but feel he had temporarily and deservedly lost. Mr. Matthews's apology was accepted.

THE CHELSEA ELECTRICITY SUPPLY COMPANY, LIMITED.—This Company has been formed with a capital of £100,000, in 20,000 shares of £5 each and 500 founders' shares of £1 each, to establish a central station for the supply of electricity for lighting and other purposes in Chelsea.

THE LIGHTING OF CHARTERS TOWERS (QUEENSLAND) WITH GAS.—By advice just received from Australia, we learn that the gas-works at Charters Towers, a town of about 10,000 inhabitants in Queensland, were started with great success on the 2nd ult. They were put up by Messrs. J. Coates and Co., of London and Melbourne.

THE THIRLMERE WATER SCHEME.—The Manchester Corporation have just let the fifth contract for the Thirlmere water scheme, which will bring the watercourse to within a mile of Lancaster; Messrs. McCreagh and McFarland, of Belfast and Londonderry, being the successful tenderers. This length of the aqueduct will be 16½ miles altogether; and the amount of the contract is £141,424 11s. 3d.

THE YEADON LOCAL BOARD AND THE WATER COMPANY.—At a recent meeting of the Yeaddon Local Board, it was reported that Messrs. Watson, Dickens, and Watson, the Solicitors of the Yeaddon Water Company, were about to make an application to the High Court of Justice for the setting aside of the award of the Umpire in the arbitration proceedings between the Company and the Board. After some discussion, the Clerk (Mr. C. J. Newstead) was instructed to take such steps as he thought necessary for proving the validity of the award.

LONDON WATER-METER COMPANY, LIMITED.—A Company has been registered under this title, with a capital of £18,000 in £10 shares. They intend "to carry on the trade of engineers, smiths, machinists, and manufacturers, patentees, vendors, and lessors of water-meters, water-motors, blowers, and fans, and all descriptions of engines, plant, and machinery; to purchase or otherwise acquire English, colonial, and foreign patent rights and privileges, improved or secret process, for or in respect, or in any way relating to all or any of the objects aforesaid, or any objects, and to use, exercise, develop, or grant licenses in respect thereof, sell, or otherwise deal with any property and rights so acquired."

THE LIGHTING OF THE TEES BY GAS.—Last Wednesday, Mr. Vivian, a representative of the Elder Brethren of Trinity House, London, visited the Tees, in accordance with the request of the Tees Conservancy Commissioners, to inspect the lighting arrangements of the river, in view of the change in the system of lighting proposed by the Commissioners—from oil to compressed gas. Mr. J. H. Amos (Secretary), Mr. J. Fowler (Engineer), and Mr. Joplin (Resident Engineer), with several members of the Tees Conservancy Commission, met Mr. Vivian, and explained the proposed scheme, which is similar to that now in use on the Clyde and other rivers. Its adoption, it is expected, will render the lighting more efficient; and will eventually be much more economical, although the change will involve an outlay at first of, it is estimated, about £3000 or £4000.

CREDITON WATER SUPPLY.—Mr. S. J. Smith, C.E., one of the Local Government Board Inspectors, held an adjourned inquiry at Crediton last Wednesday with reference to the application of the Improvement Commissioners for power to borrow £10,000. The Inspector stated that the adjournment was caused through his requiring further and more exhaustive tests to be made of the source at Walsen; also to consider a competitive scheme by Mr. J. Carthew, and that analyses from the two supplies might be made by the authorities in London. Mr. Moon submitted a long report, showing that the minimum at shaft No. 1 was 56,000 gallons, and 51,414 gallons at No. 2. Mr. Appleton stated that he had reckoned the population at 4200; and, allowing 15 gallons per head, there was ample margin for all contingencies. The Four Mills scheme was then gone into. Mr. Marten, C.E., presented a long report, contending that there was sufficient power to convey the water to all parts of the town, with the exception of a few months during the year. Further evidence was taken; and it was stated that the cost of this scheme would be something like £4000 less than that of Walsen, and with a most ample supply. The Inspector stated he had been to Crediton three times to investigate this matter, had carefully taken notes of the evidence, and would report to the Local Government Board. The authorities would be informed of the result in due course.

CROYDON WATER SUPPLY.—At the last meeting of the Croydon Town Council, it was reported that the new water reservoir and other works at Addington were nearly finished; only a little rendering inside and asphalted over the arches on the outside being required for the completion of the former. Alderman Coldwells, in moving the adoption of the report, said that the new pumping station at Addington was a great success. There was no doubt they would have from there a splendid water supply; and from its elevated position all the higher parts of the town, including Norwood, would derive very great benefit. When, therefore, they had a fair chance of severing their connection with the Lambeth Water Company, they had the means at their disposal. Hitherto it had not been practicable; but the Addington Hills reservoir would render it possible to supply the whole of the borough on a future occasion. Arrangements have been made for opening the new works on Thursday next, when the Archbishop of Canterbury will attend at the Addington Wells with the Mayor and members of the Water Committee, and set in motion the engine which will pump water from the well into the new reservoir. The Mayor will afterwards entertain the Archbishop, members of the Town Council, the County and Borough Justices, and others to luncheon in a large marquee erected on the top of the reservoir, after which His Grace will be asked to open the valves of the reservoir which will admit the water into the main to supply the town.

THE KIRKCALDY WATER COMMISSIONERS AND THEIR RESERVOIR CONTRACTORS.—In the Court of Session (Outer House) last Wednesday week, Lord McLaren gave judgment in the action brought by Mr. John Ross and Mr. John Ross, jun., partners in the firm of Messrs. Ross and Son, against the Kirkcaldy Water Commissioners and Mr. A. Leslie, C.E., of Edinburgh, the Arbitrator between this firm (who were the contractors for the Commissioners' new reservoir at Harperlee) and the Commissioners, asking the Court to reduce and set aside a decree arbitral, pronounced by Mr. Leslie in certain questions that arose between the parties. By contract dated Feb. 27 and March 5, 1886, pursuers undertook to construct a storage reservoir, with its appliances, filters, &c., for the sum of £31,739 18s. 10d. Under the contract, the late Mr. J. Sang, C.E., of Kirkcaldy, and Mr. Leslie were appointed Arbitrators. Pursuers stated that when the contract was entered into, they were not aware that Mr. Leslie was also to act, in the execution of the work, as one of the Commissioners' Engineers. Pursuers began operations in March, 1886, and the decree arbitral which they wished to have set aside, applied to the ninth monthly account of work done up to Dec. 1, 1886. Mr. Leslie found that pursuers had been overpaid by defenders on that date by the sum of £148 10s. The ground of reduction was "corrupt behaviour" on the part of Mr. Leslie in his duty as Arbitrator. This his Lordship found had not been shown; and he decided in favour of the Commissioners, with costs.

DARWEN WATER SUPPLY.—For a long time the Darwen Corporation have been on the look-out for a good source of increased water supply, and a short time ago they forwarded to Dr. Frankland a number of samples of water for him to analyze and report upon. The report was read at the meeting of the Gas and Water Committee, on Monday last week—Alderman T. Lightbown presiding. Dr. Frankland proposed a number of schemes for the supply. He stated that in his opinion the water in the Dean reservoir was absolutely pure, as it contained both peaty or surface water, and drift or mineral water. According to Dr. Frankland's report, a mixture of these two ingredients is the best and purest water, as the one quality neutralizes the other, and renders the water free from all impurity. What is termed the Sunnyside Hey, or "top" reservoir, is almost entirely composed of the peaty or surface water, and requires mixing with mineral or drift water. A number of other schemes were suggested; but this met with the most acceptance. It was, however, impossible to get through all the schemes proposed, and the matter was finally deferred to a future meeting; the Gas and Water Sub-Committee being instructed to consider and report upon Dr. Frankland's statement in the meantime. It may be remembered that a short time ago a number of cases of lead poisoning were reported in the town, and this seems to have been the cause of the present action of the Gas and Water Committee.

SALES OF SHARES.—At the Mart, Tokenhouse Yard, last Wednesday, Messrs. Fox and Bousfield sold £14,500 of 4 per cent. debenture stock of *The Gaslight and Coke Company* and £10,000 of 4½ per cent. debenture stock of the *East London Water-Works Company*, together with an annuity of £2000 payable by the *New River Company*. The prices realized were as follows:—*The Gaslight and Coke Company's* stock, £7100 at £119 10s. per cent.; and £7400 at £119 5s. per cent. Of the *East London Water Company's* stock (which was sold in lots of £200 each), five lots were sold at £287; five at £286; five at £284 10s.; five at £281 10s.; five at £281; five at £280; ten at £279 10s.; five at £279; and five at £278 10s. The annuity payable by the *New River Company*, terminable in 1911, and which was put up in four lots, was sold for £31,800.—Some £10 shares in the *Croydon Commercial Gas Company* were recently sold at £22 and £22 2s. 6d. per share. A parcel of 10 per cent. £5 shares was disposed of at £11 7s. 6d. per share; and a number of £5 13 per cent. shares were sold at £14 10s. and £14 5s. per share.—Mr. A. Smith lately sold at the Snssex Hotel, Bognor, 200 fully paid-up £5 shares in the *Bognor Water Company*. A spirited contest took place, and resulted in all the shares being sold at an average price of £3 17s. 6d. each. This, we learn, is a considerable advance in value since any of the Company's shares were last submitted to public auction.

TITLE AND INDEX TO VOL. LI.

In consequence of several inquiries as to the above, we call our readers' attention to the paragraph which appeared in our issue for the 24th ult., (p. 157), and remind them that a Title-page and Index to Vol. LI. of the JOURNAL—January to June, 1888—have been prepared, and will be forwarded by the Publisher post free on receipt of a post-card.

TO ADVERTISERS.

ADVERTISEMENTS for the next number of the JOURNAL must be received by Monday, 12 o'clock noon, to ensure insertion; but as the Advertisement sheet of the JOURNAL is sent to Press the first thing on Monday Morning, Advertisers will please bear in mind that Orders for Alterations in or Stoppages of PERMANENT Advertisements should be received Not Later than Two o'clock on SATURDAYS.

Telegraphic Address: "GASKING LONDON."

THE JOURNAL OF GAS LIGHTING, WATER SUPPLY, & SANITARY IMPROVEMENT.

TUESDAY, AUGUST 7, 1888.

THE REPORT AND ACCOUNTS OF THE GASLIGHT AND COKE COMPANY.

The report of the Directors and the accounts relating to the past half-year's working of The Gaslight and Coke Company have been issued; and it is therefore possible to see whence comes that startling amount of £277,563 which remains to be carried forward, according to the preliminary notification of the Board, after providing for the increased dividend of

13 per cent. The term which we employ to characterize this result will not be regarded as exaggerated when it is remembered that the price of gas to private consumers was reduced at the beginning of the year by 3d. per 1000 cubic feet, which is an apparent loss of revenue of about £100,000; besides which there is the additional £20,000 required to pay the extra $\frac{3}{4}$ per cent. dividend, and that eighteen months ago, with gas 3d. per 1000 cubic feet dearer, the Company were apparently not earning their smaller dividend of 12 per cent. The question that naturally arises in the mind of an observer of the Company's career is how these kaleidoscopic changes in the accounts can be explained; but this is precisely the query which we cannot pretend to answer. It may be perfectly right and reasonable for a Gas Company's unappropriated balance to dance up and down, half year after half year, in this bewildering fashion. We do not pretend to lay down a rule upon such a subject; but if for a year or two a Gas Company go on eating into their cash reserve in order to pay dividends until it is within an ace of disappearing altogether, and at the same time demands for a reduction of price are met with a *non possumus* from the Chair, and then, by a stroke of the pen, a sweeping reduction of price and an increased dividend appear in conjunction with great additions to the undivided balance, we simply confess that the case is beyond our comprehension. How is a critic to ascertain the real position of such an undertaking? No sooner does he shake his head over a disappearing reserve and the pessimistic observations of a Chairman who professes disbelief in the efficacy of reductions of price to increase business, than the situation changes with the rapidity of a dissolving view, and the "winter of his discontent" is made "glorious summer" by some occult means. When this matter was discussed in February last, Colonel Makins, M.P., the Governor of the Company, admitted that the Board had been applying the undivided balance to purposes that might have been secured by calling up fresh capital. It now appears, however, that the need for this proceeding has ceased, for the reserve is going up again "by leaps and bounds," and yet the capital account has not been swollen by fresh subscriptions. It must therefore be understood that in setting out the various items of the accounts of The Gaslight and Coke Company according to custom, we do not draw any particular lessons therefrom with respect to the financial position of the concern. The figures must speak for themselves.

The report is, as usual, brief, not to say curt. It recites the principal figures relating to the results of the half-year's working; showing that the undivided balance has been increased from £230,294 to £277,563. The shortest possible reference is made to the prospective lapse of the coal dues next year, the effect of which upon the business of the Company is not discussed in any way. The withdrawal of the Bill by which the Metropolitan Board of Works sought to regulate the position of gas-mains in London thoroughfares is noticed; and there is a paragraph explaining, and at the same time defending, the action of the Board in carrying to the House of Lords their litigation against the South Metropolitan Gas Company. They say that this extreme step was forced upon them by the legal advice which they took in the interest of the Company. Upon this it might be remarked that it is no trouble to lawyers who happen to have rich clients to recommend the pushing of litigation to the uttermost. For the shareholders and the public, on the other hand, one may repeat the well-known expression of gratitude for the existence of a House of Lords, because here the matter must stop. The customary official reports relating to the condition of the works and plant are given. Mr. G. C. Trewby, the Engineer-in-Chief, reports that the last of the Beckton retort-houses is being fitted up, to come into use next winter, when it is expected to be wanted to cope with the increased demand. It is a curious question, although it may be an idle one, but where does the money for this extension of manufacturing plant come from? Is it all included in the large sum of £539 which is the whole allowance for "buildings and machinery" in extension of works appearing in the capital account? It is miraculous; but, on the face of it, we must credit Mr. Trewby, of whose merits as an engineer and gas maker we have a sufficiently high appreciation, with the ability to provide carbonizing plant for an additional output of $5\frac{1}{2}$ million feet per day at a cost of not exceeding £1 per million!

According to the revenue account, it appears that the Company received for common gas, sold at 2s. 9d. and 2s. 5d. per 1000 cubic feet, the sum of £1,090,735, as compared with

£1,161,625 for the corresponding half of 1887, when the price was mainly 3s. per 1000 cubic feet. Thus the loss of rental by the reduction was £70,890. Taking the total gas revenue of £1,205,433, and comparing it with the £1,289,751 for the corresponding period of last year, the diminution is £84,318, which is £20,000 less than is shown by a calculation disregarding increase. Stove and meter rental shows an expansion; and residuals have improved by £27,452, notwithstanding a disappointing falling off in ammoniacal liquor and sulphate. Altogether, the revenue stands at £1,576,301, as compared with £1,632,335 for the corresponding date last year. On the other side of the account, it will be seen that there is a further saving in coals, which cost £538,353, as compared with £546,650. The coal bill has remained about the same, or rather has fluctuated within the same range, during several years past. Wages and salaries have slightly increased, in consequence of there having been a greater weight of material to deal with. Purification is also a little more; but repair and maintenance is again less. Under the head of distribution, there is evidence of strict economy—salaries and wages and repairs and maintenance alike showing reduction of expenditure. The other entries on this side do not call for particular comment. The total expenditure on revenue account, notwithstanding the increase of nearly 2 per cent. in the quantity of gas sold, has been diminished from £1,030,406 to £1,010,389, or by nearly £20,000. The net result of these decreased expenses and revenue is a balance of profit of £565,911, as compared with £601,929 for the corresponding half of last year. The other accounts may be quickly dismissed. The coal account shows that 896,802 tons in all were carbonized, including 9804 tons of cannel. For the June half of 1887 the weight was 884,650, including 18,422 tons of cannel. This is a great improvement, upon which we heartily congratulate the Company's Engineers. The total quantity of gas sold was 8,707,896,000 cubic feet; showing an increase for the year of 1.95 per cent. This rate of growth, although not large, is in a manner satisfactory under the circumstances. It only remains to be stated, in evidence of the demand for coke for general consumption, that the value of the stock of this residual in the general balance-sheet is only taken at £4530. When the Governor meets the proprietors on Friday he will not have much to tell them, unless he goes considerably outside the figures of the accounts; for these are of the quietest, not to say most humdrum, aspect as they stand. There will, of course, remain for him the central mystery of the Company's fluctuating reserve; and he may be expected to say something about the success of the attempt now being made by the Company to win patronage from cottage occupiers. This latter is a subject upon which curiosity widely prevails.

THE REPORT AND ACCOUNTS OF THE SOUTH METROPOLITAN COMPANY.

THE report of the Directors and the accounts of the South Metropolitan Gas Company for the past half year are in the hands of the proprietors to-day; the ordinary general meeting being called for to-morrow week. The report is not very long; but the matter of it is a sufficient indication of what the Chairman, Mr. George Livesey, will talk about when he meets his constituents. The Company's rate of increase is 4.7 per cent., compared with the consumption for the corresponding period of last year. Either building is progressing more rapidly on the south than on the north side of the Thames, or the South Metropolitan gas is more popular than that of the Chartered, to account for the more rapid growth of the smaller Company. We incline to the former opinion, as being a better explanation of the facts. The South Metropolitan Company's revenue from residuals has improved by £22,061; but they still burn 39 per cent. of the total make of tar for fuel. Reference is made in the report to the district gas exhibitions which have been held under the auspices of the Company during the past winter and spring, leading to an increased demand for gas-stoves. The opportunity is taken for saying a good word for regenerative and other improved kinds of gas-burners for lighting purposes. The prospective lapse of the coal dues is commented upon in a congratulatory spirit. The Directors lay claim to a share in the successful opposition to the renewal of the dues; and declare that when the unjust tax is removed they "intend to give the entire benefit of the saving thereby effected to the consumers." The dividend of 13 per cent. has been earned upon the revenue account; leaving a balance of £11,085 to be carried forward. From the revenue account, it appears that the gas-rental for the half year amounted to £337,979, as compared with £329,868; showing an increase of £811,

as stated in the report, notwithstanding the effect of the reduction in price since March, 1887. The question therefore arises: Will the Directors take off another 1d. per 1000 cubic feet now, or wait for the expiry of the coal dues to take off 2d.? Coals stand the Company in £158,527, which is £5000 more for the half year; and repairs and renewals are considerably higher. So that, altogether, gas manufacture costs the Company £245,801, as against £228,932. Distribution also rose from £18,146 to £21,291. Most of the other items on the debit side are heavier; and consequently the total expenditure is £310,694, as compared with £288,457. Yet the balance carried to the net revenue account is £144,763, as compared with £136,956 a year ago. The other accounts are nowise remarkable. The Company have only £291 worth of coke and breeze in store. They carbonized during the half year 291,967 tons of coals, including 1982 tons, or 0.67 per cent., of cannel. This is a falling off from a year ago, when only 594 tons of cannel appeared in the accounts. Possibly Mr. Livesey will lay the blame for this upon his aversion, the "Tower" photometer. The general meeting will not find much to complain about in these accounts, which, as the report justly remarks, present the working of a period that may be truly described as "uneventful but satisfactory."

RESIGNATIONS FROM THE GAS INSTITUTE.

A SPECIAL meeting of the Council of The Gas Institute was held on Tuesday last, when, as we anticipated a fortnight ago, the resignations of twelve gentlemen were received, including all the Trustees, all the Vice-Presidents, all the Finance Committee, and the ex-President. The notification of this portentous secession was conveyed to the members on Saturday last by circular from the President, Mr. Henry Woodall, who now finds himself in a position more extraordinary than that occupied by any of his predecessors in office. To all intents and purposes he is now the Institute. It is a position of peculiar difficulty and responsibility, but also of unrivalled opportunity. It was a wise man who said that difficulties are opportunities; and Mr. Woodall has now an exceptional chance for showing the stuff of which he is made. Fortunately, the members of the Institute have the satisfaction of knowing that Mr. Woodall is a man in whom they can implicitly trust. He is not one to leave difficulties to settle themselves; and his interest in the Institute is such that he will study to preserve it, while committed to his charge, from the wreck that seems to threaten it. He does not lack courage, moreover, to persevere in any course that may appear to him to be right, in defiance of what envy and malice may do to hinder him. He has already taken the first step towards grappling with the evil that has overtaken the Institute, in asking for the confidence of the members. In the same circular in which he announces the resignation of so many of his former colleagues, he requests the members generally to refrain from taking similar action until he has had an opportunity of laying before them, in an extraordinary general meeting, the proposals which he has to submit for dealing with the situation. This is a very reasonable demand, and it is to be hoped that it will be granted. The first impulse of a great many members, upon hearing of the withdrawal of the gentlemen named in the circular, would naturally be to follow their example. But in an emergency of this kind, personal inclination should give way to consideration for the general good; and, in holding their hands for a time, until they learn the President's solution of the difficulty, members will not forfeit their right of action, while at the same time they may save the Institute. The undertaking has now been definitely given that an extraordinary general meeting of the Institute will be convened in the autumn, at which it may be presumed that the President will take serious counsel with the members respecting the position of the organization. Upon the transactions of that meeting will depend not merely the success of the ordinary meeting which should be held next June, but also the future existence of the Institute. The President is deeply committed to remove the crisis by his request to members to suspend their own action until he can explain his views. If the extraordinary general meeting should reject his recommendations, he will have no other course open to him than to leave the chair and the Institute. The gravity of the issue will therefore ensure well-considered action upon Mr. Woodall's part, as it should inspire members in general with an earnest resolve to help him in the performance of his difficult and delicate task. If he is only properly supported, there is little reason to fear for the President; and we trust that evil influences have not prevailed

so far as to render doubtful his obtaining from a body of professional colleagues and fellow-countrymen that help and countenance which any man in his position has a right to expect.

MR. BRAY AND THE ROCHDALE GAS ENGINEER.

It is to be hoped that anybody who may have allowed himself to fancy that Mr. George Bray is an injured innocent, a pattern of magnanimity oppressed by a vile combination, a man with an honest grievance which he only wants to ventilate in a legitimate way and to see disposed of, for or against himself, in a fair manner by competent authority, will attentively peruse the letters reprinted in another column, which Mr. Bray has addressed to the Editor of a Rochdale paper with reference to Mr. T. Banbury Ball, the Engineer of the Rochdale Corporation gas undertaking, and for the past three years a member of the Council of The Gas Institute. Mr. Bray's last pamphlet, in which he accuses the Council of the Institute of aiding and abetting corruption, and participating in malpractices of a kind which need not be further particularized, so familiar are Mr. Bray's "charges" to readers of the JOURNAL, was, as is well known, carefully sent to all directors of gas companies and members of local authorities owning gas-works throughout the United Kingdom on the eve of the last Gas Institute meeting. At Rochdale, unfortunately for Mr. Ball, it also chanced that a question of raising his salary by £100 a year, in acknowledgment of the good service he has done to the town by his successful management of the gas undertaking, was then before the Council; and, as usual, there was a lack of unanimity upon the point. Mr. Bray's pamphlet came as a welcome aid to the opponents of Mr. Ball's rise; and, after a sharp struggle, he only obtained £50 instead of £100 a year additional pay. The Mayor of Rochdale may be an amiable and right-thinking, but he appears to be a decidedly weak gentleman; for, after declaring in public clearly enough what he thought of Mr. Bray's conduct in this matter, he seems to have been rather frightened when turned upon by this redoubtable pamphleteer. Finding the Rochdale people softer than were the Widnes Local Board when he attempted to make Mr. Isaac Carr suffer in his official position for daring to express his opinion in a Gas Institute meeting, Mr. Bray proceeded to worry Mr. Ball shamefully, as appears in the letters in question. He could not allege that Mr. Ball had anything whatever to do with the matters that constitute his old grievance; but he "charges" him, as with a deadly crime, that he has not taken his part! That is the sum and substance of Mr. Bray's complaint against Mr. Ball, for which he, a wealthy manufacturer with nothing material at stake, assails his victim through the means whereby he earns his bread. These may be practices which honour a person who is said to be an ornament to the best Leeds society; but it remains for members of The Gas Institute to reflect whether they will be content to sit in company with the individual who thus persecutes one of their own order and number. It must be remarked that this onslaught of Mr. Bray on Mr. Ball, and his attempt to bully the Rochdale Gas Committee into making an inquiry, not merely into the conduct of their own paid official—they have done this, and are content, to Mr. Bray's disgust—but also into everything he has to say about the Electric and Gas Exhibition with which Mr. Ball was not connected, is not to be excused as an irrepressible ebullition of temper on the part of a down-trodden man. It is after the Council of the Institute had consented to the perpetual injunction restoring Mr. Bray's name to the list of members that he thus assails Mr. Ball, because he happened once to be a member of the Council. In view of these proceedings, the question has now become a personal one for every gas manager in the kingdom who does not happen to be in Mr. Bray's list of supporters. He now finds that he cannot touch Mr. G. Livesey. After so many years of vilification, it must be gall and wormwood to Mr. Bray to learn of Mr. Livesey's appointment to the honourable office of sole arbitrator and valuer in connection with the Edinburgh gas-works transfer. He has tried his little utmost to persuade the world that Mr. Livesey is something undistinguishable from a thief and a liar, by formulating and reiterating for years, at great expense, a farrago of "charges," in which this imputation is conveyed as explicitly as is consistent with the observance of a particular degree of caution in keeping on "the windy side of the law;" and now, after all, the object of his abuse is selected as the administrator of the most important affair of recent years, as far as the gas supply of the United Kingdom is concerned. We have maintained all along that Mr. Bray's venom was too stale and his shafts too weak to

really hurt Mr. Livesey; and this news is proof in point. After this, it would be impossible for Mr. Livesey to go into Court and swear that Mr. Bray has done him any particular injury up to the present time. Failing in his old line of attack, therefore, Mr. Bray has turned to objects of resentment which he has reason to believe are more within his reach. It is a bad look-out for the poor gas manager, if, whenever he asks for an increase of salary, he is to have Mr. Bray's pamphlets and letters thrown at his head, in addition to the stock objections of cheeseparing Bumbledom.

Water and Sanitary Affairs.

THE opening of the new storage reservoir of the Grand Junction Company at Ealing, of which a full account will be found elsewhere, is one instance among many others, showing the spirit of progress which animates the Metropolitan Water Companies. At the same time that the Company were seeking authority from Parliament to carry their intake higher up the Thames, they were expending a large sum of money in the construction of the splendid reservoir inaugurated last Friday. It may, indeed, be questioned whether any public authority, in the absence of a general complaint alleging deficiency in quantity or quality, would have been found equally willing thus to expend capital for the improvement of their supply. No doubt there are cases in which Municipalities have devoted large sums to the construction of water-works; but it has frequently happened that they have waited until pressed to this performance by dire necessity. The London Water Companies are not in the habit of waiting, but have anticipated the time of need, although checked rather than encouraged by Parliament in their efforts for this purpose. The miserable suspicion has been fostered that the Companies were less anxious to fulfil their duty to the public than to increase their capital account, in view of a coming day when they would have to be bought up. The idea is absurd, and altogether unworthy. The Companies are by no means sure they are going to be bought up; and if they were, a sordid policy would induce them to starve their plant and pay high dividends, instead of improving and extending their means and appliances, so as best to serve their customers. It is to be hoped, if occasion should require, that Lord Knutsford will be able to enlighten the Cabinet as to the real position and policy of the London Water Companies. It will be seen that Sir Roper Lethbridge, who represents North Kensington, predicted in his speech at Ealing that the transfer of the London Water Supply to a public authority was probably not far off; and his chief hope of fair treatment for the Companies was founded on a right understanding of the subject being arrived at—both in and out of Parliament. All that the Companies ask for is fair play. Baron Dimsdale spoke somewhat in the same vein as Sir R. Lethbridge, and anticipated a struggle. Dr. Tidy's opinion was that if ever the London Water Companies were superseded by a public authority, there would be an end to the construction of extensive works for the purpose of improving and enlarging the supply. It may be thought that these remarks are somewhat controverted by that which appears in connection with the opening of the new water-works at Croydon—an event which took place the day before the inauguration at Ealing. But it should be noted that, while the Croydon Corporation (or the Local Board which preceded the incorporation of the borough) were supplying the lower levels, the Lambeth Company were giving a supply to the higher and outlying portions of the district. After the lapse of many years, the local authorities are smitten with a zeal to give a supply where one is already bestowed. The Lambeth Company were first in the field; and, having statutory rights, will have to be bought out, or else be allowed to remain. But for the Company, a considerable area where the land is high would have been left for a long time without any water supply except what could be obtained from private wells. As for the higher charges levied by the Lambeth Company, it is quite possible that some explanation may be forthcoming. The case is probably exaggerated; and it is tolerably certain that the facts are not fully told. One thing is clear, that the high-level service was given by the Lambeth Company when the local authorities were wholly unable to offer it. So far, the inhabitants are debtors to the Company, rather than to the Local Board or the Corporation.

A report by Dr. Percy Frankland on the bacteriological character of the London Water Supply during the year 1887

has just been published in the monthly report of the Metropolitan Water Examiner, General A. de Courcy Scott. The elimination of micro-organisms, as effected by the filtration processes of the Water Companies, is found to vary from 93.9 per cent. in the East London supply, to 99.6 per cent. in the West Middlesex. The New River samples are not included in this statement, as there are complications affecting the supply which render it unsuitable for comparison. The differences shown may be taken to indicate different degrees of excellence in the mode of treating the water after its reception at the intake. Dr. P. Frankland intimates that the comparison is important, and so it undoubtedly is, as pointing to the best modes of storage and filtration. Necessarily, the Kent supply, as taken from chalk wells, is excluded from the comparison. In that case it generally appears that there are more micro-organisms in the supply than in the source. The annual average is to this effect, the three wells having respectively 16, 18, and 27 organisms per cubic centimetre, while the supply averages 106. But the average number of organisms in the Kent supply is less than that in any other, except the New River and the West Middlesex. These last two have an average of only 81 and 87 organisms. The highest average occurs in the East London supply; the number being 806. Accompanying the annual report, we have Dr. P. Frankland's statement for the month of June last. This shows 219 micro-organisms per cubic centimetre in the Kent supply, which exceeds the number in all the other supplies except the East London. Even the Kent wells are rather abundant in microbes, the Garden well having 71, which exceeds the number in all the river supplies except two. But we have only to consider the thousands of micro-organisms contained in a cubic centimetre of unfiltered river water, in order to be persuaded of the admirable effect of filtration as practised by the London Water Companies. Dr. P. Frankland's researches are thus of very special value.

THE TRANSFER OF THE EDINBURGH GAS-WORKS.—The Works Committee of the Gas Commission of the Edinburgh and Leith Corporations, which has just been constituted to manage the two gas undertakings recently acquired by the Corporations, have arranged with the Directors of the two Gas Companies concerned that Mr. George Livesey is to be sole arbitrator and valuer, under the 20th section of the Corporations' Gas Act, as far as regards the valuation of the stocks, stores, &c., in hand at the date of the transfer.

THE GAS INSTITUTE AND THE RESIGNATIONS FROM THE COUNCIL.—Under date of Aug. 2, the following letter (signed by Mr. Henry Woodall, President, and Mr. W. H. Bennett, Secretary) has been issued to the members:—"At a special meeting of the Council held on the 31st ult., resignations were received from the following gentlemen:—

G. C. TREWBY	H. HACK	R. MORTON
W. FOULIS	C. HUNT	C. GANDON
G. LIVESEY	J. L. CHAPMAN	T. MOORE
F. LIVESEY	C. WOODALL	T. NEWBIGGING.

And it was resolved—"That notification be made to the members generally of the resignations which have taken place in the Council, and that they be requested to refrain from acting similarly until they be called together in General Meeting." An extraordinary general meeting will therefore be convened in the course of the autumn."

THE PROPOSED CONSTANT SUPPLY OF WATER IN THE CITY.—The Gas and Water Committee of the Corporation of London, having had interviews with the Superintendent of the New River Company (Mr. Collins) and Mr. Archibald Dobbs, have come to the conclusion that it is not expedient to take any steps for obtaining a constant supply of water to the City. In a report lately presented to the Common Council, embodying this recommendation, they say that the constant supply to the parish of St. Pancras was estimated to cost the owners or occupiers at least £5 each for the requisite fittings; and that in the City, owing to its exceptional circumstances, the expense would probably be considerably more. There was also danger of pipes bursting under the high pressure, and causing much damage to property. In connection with the foregoing, Mr. J. Hauser, the Honorary Secretary of the Mansion House Council on the Dwellings of the People, has written to *The Times* to point out that the expense alluded to was incurred only by the owners or occupiers of houses situated in that part of the parish of St. Pancras which is supplied by the New River Company, and that the owners or occupiers of houses situated in the area of the West Middlesex Company, and to which constant supply has been given, have only exceptionally been compelled to incur the outlay. He says the difference appears to be that the former Company have proceeded on the assumption that the water-fittings in every house were defective, while the latter only required alterations of fittings when they were found to be faulty. Hence the expense of constant supply to which a householder may be put is dependent rather upon the locality of his house than upon the condition of its water-fittings.

Essays, Commentaries, and Reviews.

GAS AND WATER COMPANIES IN THE STOCK MARKET.

(FOR STOCK AND SHARE LIST, see p. 259.)

THE course of business in the Stock Markets during the past week has not presented any very noticeable feature beyond slight fluctuations. These have been mostly in the Home Railway Department, and produced by the variations in the weather as affecting traffics. There has been nothing stirring abroad to agitate foreigners. Business throughout is beginning to get quiet; and in view of the Bank Holiday there was scarcely anything doing at the close of the week. The Gas Department has not, however, been without interest. On Thursday, advantage was taken of the issue of the prospectus of a new Electric Light Supply Company, to knock down the stocks of the Metropolitan Gas Companies in a fashion which calm reflection will show to be wholly unreasonable. We have nothing to say against the new project, which appears to be associated with names of respectability and of scientific eminence; and that is something in its favour. But the future is all *in nubibus*; and it remains to be seen what they can do, and whether they will be more successful than their predecessors and contemporaries in supplying a constant light at commercially remunerative rates. Anyhow, the "bearing" of gas stocks upon the mere announcement of the Company is a rig and a trick of the most transparently artificial character, and we trust too apparent to frighten even timid shareholders to throw their property on the market. Indeed, quiet as Saturday was, there was some recovery made from the fall. Gaslight "A" was done once for an exceptional amount at a special price as low as 250—a very enviable figure to purchase at, too. The closing transaction on Saturday, however, was 256. Altogether the stock has fallen 3½ in the week. The "B," which is a limited maximum stock, has risen 2; and comparing it with the "G," we are again confronted with the anomaly of a deferred stock commanding a higher value than a preferred one. All three South Metropolitan are lower, but not much; and Commercial old marks a slight fall. The other changes, though slight and unimportant, are in the upward direction. The Water Market has been quiet; and the stocks (especially Lambeth 10 per cents.) still move up.

The daily operations were: A quiet market on Monday; more being done in South Metropolitan "B" than anything else. Water was wholly neglected—all quotations were unchanged. Rather more activity on Tuesday. Imperial Continental rose 1, and European ½; but Gaslight "A" was 1 lower. Water was very stagnant; but Chelsea, East London, Grand Junction, and Kent advanced 1 each, and Lambeth 2. Gas was much busier on Wednesday, and prices were very fair. The only move was a rise of 1 in Australian. Water was as before. Thursday was the crisis in Gas, when Gaslight "A" fell 4½; Commercial Old, 2; and South Metropolitan "A," 4, "B," 1, and "C," 5. But Gaslight "B" improved 2. Friday was quieter; and Metropolitan Gas issues were steady; but Imperial Continental lost the 1 it had gained on Tuesday. There was more activity in Water, at existing figures. On Saturday there was a rally, and Gaslight "A" recovered 2. Water was very quiet; but Lambeth 10 per cents. rose 1 more, and New River debenture 1½.

ELECTRIC LIGHTING MEMORANDA.

THE PROSPECTUS OF THE METROPOLITAN ELECTRIC SUPPLY COMPANY—TWO MORE OF "GRANDFATHER BRUSH'S" PROGENY GONE—CHELSEA ELECTRIC LIGHTING SCHEME—ELECTRIC LIGHTING ENGINEERS IN COMPANY.

THE prospectus of the Metropolitan Electric Supply Company—which is the concern that has been repeatedly mentioned in this column of late, with the now meaningless prefix "South" omitted from the name—was issued last week, and the subscription list was open for Friday only. It is reported that the public "jumped" at the shares; the prospects of the Company being regarded as remarkably good. Much of this favour was, of course, due to the names on the Board. Any electrical speculation fathered by Sir John Pender, Admiral Sir George H. Richards, and men of similar standing, would be certain to go off well. The capital of the Company is to be £500,000, more than half of which was to be applied for by some of the Directors and their friends. The chief thing we can see against the Company is the presence of two electrical engineers upon the Board, and three others as consultants. If two of a trade ever did agree, in despite of the old saw, they were not electric lighting engineers identified with irreconcilable systems. The public are likely to be taken with the declaration with which the prospectus begins, to the effect that the Directors (who, as pioneers of submarine telegraphy, ought to know what they are talking about) have come to the conclusion that the time has at length arrived when "the great work of electric lighting may be undertaken on a scale which will largely meet the requirements now supplied by gas." The rest of the prospectus is couched in a similar strain; and the financial aspects of the proposed investment are compared with the condition of London gas stocks. The Directors kindly forbear from expressing an opinion as to the extent to which gas will be used in the future; but take the opportunity for declaring their conviction that electric lights will largely supersede all others. They state that Electric Lighting Companies in the United States are now actually paying 8 to 20 per cent. dividends; and we trust that this is correct. The first work of the new Company will be to acquire the undertaking of the Whitehall Electric Supply Company, who secured a promising "pitch"

for lighting sundry hotels and other blocks of buildings lying between Whitehall and the Thames Embankment, as well as a convenient wharf and site for a generating station near to Waterloo Bridge. After they have made a start, the Company promise to do wonders, of course; but it will be time enough to congratulate them when they can show something. Lest our reserve upon this point should appear to spring from prejudice, we will quote the opinion of the *Electrical Review*, which is to the effect that "the financial and speculative, rather than the truly commercial element is too strongly represented on the Board; and we therefore have misgivings as to the future of this Company which even the respected names of the distinguished men associated with the scheme as Consulting Engineers entirely fail to remove."

An extraordinary general meeting of the South-Eastern (Brush) Electric Light and Power Company was held last week, under the presidency of the Liquidator, to adopt the report and accounts relating to the winding up of the Company's affairs. It appeared from the statement submitted to the meeting that the total loss of the Company has been £45,958, after everything has been realized. The meeting was followed by another called in the name of the Provincial (Brush) Electric Light and Power Company, with the same Liquidator in the chair. The loss in this case has been £51,096. During the proceedings, a shareholder declared that "the inception and management of the two Companies had been a stain on the commercial morality of the City." Thus ended the life of two of the Brush spawn, of which such great things were prophesied. The shareholders would dearly like to prosecute the promoters, or directors, or somebody connected with these speculations; but the Liquidator has looked into the matter, and does not think that any good would come of such a step. Thus another example of robbery under the protection of the law of joint-stock companies has been placed upon record.

The Chelsea Electricity Supply Company has been launched; and we believe the Directors have received sufficient support to warrant them in proceeding to allotment. This is nothing more than an offshoot of the Brush Company, the Electrical Power Storage Company, and Callender's Bitumen Telegraph and Waterproof Company, who have all kindly agreed to take payment for their goods in shares. It is, of course, intended that the Brush Company should provide the machinery and lamps; the Electrical Power Storage Company, the secondary batteries; and the other concern, the cables. If independency of any particular company or system is the recommendation that it is made to appear in the prospectus of the Metropolitan Electric Supply Company already noticed, the reverse must be no advantage to this venture. It remains to be seen which principle the more commends itself to public favour; but, remembering what has happened before now to scions of the Brush stock, we should rather be disposed to doubt the advantage of ascribing the parentage of a new concern to this source.

Some time ago an attempt, in which our friend the *Electrical Review* was implicated, was made to form a kind of electrical trades union, or rather it should be described as a proposed "ring" of electric lighting apparatus manufacturers, with the object of regulating prices and stamping out unfair competition in trade. The attempt failed from the impossibility of formulating an acceptable scheme. But the other day the idea was in part revived; and this time the proposal was to form an Electrical and Allied Trades Section of the London Chamber of Commerce. A preliminary meeting has been held, under the presidency of Mr. Crompton; and a Provisional Committee of fourteen appointed to organize the proposed section. The project appears to be popular, at least among London members of the trade; but what the good of it is to be we cannot at present understand. The electric lighting engineers appear to be a very jolly and social set of fellows, at any rate; for although they are necessarily living in the sharpest competition with each other, and are always treading on one another's toes in the matter of patents, they are ever ready to meet formally or informally, at a dinner or in a lecture-room, and combine for pleasure or business purposes with a cheerful alacrity that might be emulated with advantage in other callings. The reason for this probably is that they are all educated gentlemen. It requires an underbred man to be spiteful and jealous in business relations.

THE issue of a small pamphlet on "Electric Lighting: Its Present Position and Future Prospects," by Messrs. Hammond and Co., has, according to the authors' preface, been called for by a desire expressed on the part of a number of friends of the firm to have a detailed explanation of the "advantages of the present methods of electric light supply, as compared with those which failed five years ago." In a book with such an object, it is only natural to expect that stress would be laid on what are called the "disadvantages" of the older form of illuminants; and this we find has been done. The superior qualities of the new form of illuminant are extolled, and the various appliances used for its production and use are explained by the aid of diagrams. Then the important question of the possibility of a remunerative return to capitalists starting central electric lighting stations is discussed; and the book closes with a number of estimates of the cost of different sized plants, from a 1000 to a 20,000 light installation. The authors refer to the difficulties which have hitherto stood in the way of house-to-house electric lighting; and these having, as they consider, been overcome, they are led to anticipate a successful future for the system they advocate.

NEW STORAGE RESERVOIR AT EALING.

ON Friday last, at the invitation of the Directors of the Grand Junction Water-Works Company, a numerous assembly of persons interested in the water supply of the Metropolis came together at Mount Park Hill, Ealing, to witness the opening of a new storage reservoir of great capacity. Among those present were Mr. E. Goodhugh Fox, the Chairman of the Company, and several of the Directors, including Mr. C. J. B. Hertslet, and Mr. F. Tagart. Among the visitors were Baron Dimsdale, M.P., Sir C. J. Palmer, Bart., Sir Roper Lethbridge, K.C.B., M.P., Sir Robert Rawlinson, K.C.B., Major F. S. Rasch, M.P., Mr. John Aird, M.P., Major-General A. de Courcy Scott, Professor Edward Frankland, Professor Corfield, Dr. C. M. Tidy, Dr. Percy Frankland, and Mr. Philip A. Scratchley, with most of the Secretaries and Engineers of the London Water Companies, and several Medical Officers of Health of Metropolitan districts, together with others from the neighbourhood.

The reservoir occupies a commanding situation on the rising ground to the north of Ealing. Being of a great depth, it was seen to advantage on Friday when empty, and was much admired as a specimen of engineering work. The Contractors (Messrs. John Aird and Sons, of Lambeth), have had a difficult task, owing to the generally unfavourable state of the weather, and the circumstance that the site is on a hillside. The net time consumed in the entire construction has been scarcely thirteen months—an astonishingly short period for so extensive and arduous an undertaking. When filled, the reservoir will have a surface area of six acres, with a depth of 45 feet, and will contain 51 million gallons of water, having a top level more than 100 feet above the surface of the ground at the Marble Arch. The floor of the reservoir is composed of one foot of Portland cement concrete, underneath which is the natural clay, puddled in places where requisite. The slopes on the sides are paved with vitrified bricks, backed by concrete 1 foot thick, and 1 ft. 6 in. of puddle. The Company's intake is at Hampton, whence water is conveyed to the Kew Bridge works. From Kew a supply will be pumped up for a height of about 160 feet, through a 30-inch cast-iron main, into the Mount Park reservoir. The purpose of this reservoir is to fulfil a supplemental part in relation to the others already existing. It is intended as a reserve in case of emergency, such as might arise in connection with a large fire, or in consequence of a season of unusual drought. The leading idea is to fill it by pumping up from Kew at odd times during the winter; the supply being taken out more especially during the summer. As the work will thus be intermittent, the water will be made to enter and leave the reservoir by the same main. The entrance from Kew is into a main valve-shaft, 50 feet deep, situated just outside the reservoir at the south-west angle. Thence the water will pass into a small pit under the floor of the reservoir, and rise through a grating into the reservoir itself. Outside the opposite extremity of the reservoir is an open filtering-shaft, circular in form, having a diameter of 65 feet, and a depth of 44 feet to the level of the sand. A portion of the area is occupied with gravel. Here the water will undergo a filtering or straining process on its way from the reservoir into the main on its outer course. The actual filtration of the water takes place before it leaves Kew; but this subsidiary process at Mount Park is intended to compensate for the circumstance that the reservoir there is uncovered.

The main which receives the water from the filtering-shaft is led back under the bed of the reservoir into the main valve-shaft; the water passing into the pipe by which it originally ascended. An alternating process will thus be set up, regulated by the valves in the shaft; but the intervals between will doubtless consist of hours, and probably days. The situation of the filtering-shaft outside the northern extremity of the reservoir adds to the strength of the external embankment, which slopes down at this point to a depth exceeding 60 feet. The brickwork of the shaft goes down through the embankment 12 feet into solid ground. We may further mention the fact that a short distance from the foot of the embankment the Company are having a boring made in order to reach the chalk, which is there estimated as being 320 feet below the surface of the ground.

The nature of the ground in which the reservoir is formed is what is termed a very short clay. Only one stone was found during the whole of the excavation; and this was evidently an erratic boulder or block, brought down from the northern regions during the glacial period. It was found embedded in the clay, about 9 feet below the surface. It was set up to view on the bank at the summit of the reservoir, and attracted much notice last Friday. Its composition is a very fine sand, consolidated under pressure, and extremely hard—forming a species of quartzite.

Having explored the works, the party began to gather for the ceremony of inauguration. The Chairman, Mr. E. G. Fox, took up his station at the southern end of the reservoir; and, after giving a brief address, proceeded to open the sluice. The apparatus provided for this purpose was composed partly of brass and partly of polished wood; the latter material being obtained from a wooden water-main supposed to be a hundred years old. A plated ball at the summit of the machine contained an inscription setting forth the occasion on which the contrivance was used. A moderate amount of movement in the apparatus—in effecting which the Chairman invited the assistance of Sir R. Rawlinson, Mr. J. Francis, and Mr. C. Horsley—was speedily followed by a rush of water into the great basin destined for its reception. The effect was striking, and elicited the cheers of those who witnessed it; but, as a matter of fact, the water will come another way when there is nothing ceremonial in the transaction.

The next step in the programme involved an adjournment to a

spacious tent, erected on the lawn appertaining to the residence of Mr. A. Fraser, M. Inst. C.E., the Company's Engineer. An excellent *dejeuner* was here provided; the chair being taken on the occasion by Mr. E. G. Fox, while the two vice-chairs were occupied respectively by Mr. E. O. Coe, the Company's Secretary, and Mr. Fraser. At the close of the repast, the Chairman gave the customary toasts; and several addresses were delivered, in the course of which the Chairman explained that the absence of Lord Knutsford (one of the Company's Directors) was due to the pressure of official engagements in connection with the Government. He was also in the receipt of a letter from Lord George Hamilton, who regretted that parliamentary duties so completely absorbed his time when the session might have been expected to close. In the absence of any representatives of the House of Lords, they were happily favoured with the presence of four members of the House of Commons. On the authority of Parliament, the London Water Companies had expended £13,000,000, for which the average return at the present time was not more than 7 per cent. Some of the Companies received no dividend during the first few years of their existence—the New River Company having to wait as long as fifteen years. He believed that no city in the world was so well supplied with water as London; and it could not be said that the Companies had received an extravagant return for their outlay, and for the risk they had encountered.

In the course of the subsequent proceedings, Sir Roper Lethbridge, M.P., referred to the extraordinary attempt made during the progress of the Local Government Bill to place the Gas and Water Companies of London at the mercy of the County Council, who it was proposed should have power to take over the property of the Companies, or to establish a competing supply. The proposal was not that the County Council should obtain possession of the property of the London Water Companies by a fair payment, recognizing due compensation, but that the new authority should obtain these undertakings at mere pittance value. For this he could not vote; and he believed the House of Commons would never consent to it, though he thought it probable that at some future date the property of the Companies would be taken over by some public body. The tendency of public opinion, he felt, made such a transfer probable at a measurable distance of time. But he believed the question had only to be laid properly before the public, in order to ensure that the transaction should be carried out on terms that would reflect no disgrace on the honour and honesty of Englishmen. If rightly informed on the subject, he was confident that public opinion would never sanction anything like confiscation, but would consent to a line equivalent.

Baron Dimsdale expected there would be some more fighting over the question of the London Water Companies. The House of Commons seemed to think it was wrong for anybody to hold any description of property. But "threatened men lived long;" and the Companies would find their best guarantee for safety in faithfully performing their duty to the public.

Dr. Tidy remarked how little the water consumer understood as to the amount of skill and trouble necessary to give him his daily supply. As a chemist, he would say that, while he could admire a magnificent engineering work, he yet contended that no engineer was justified in seeking to purify a bad water. But they were perfectly warranted in seeking to improve water that was already good. They were not trying to "doctor" the supply, but to improve a water previously excellent.

Major-General A. de Courcy Scott spoke of the satisfaction it had given him to witness the expansion and improvement of works connected with the London Water Supply. Referring to the Bill of the Grand Junction Company which had been rejected in the present session of Parliament, the speaker said that the proposal to go higher up the Thames for an intake was one of which he approved in the highest degree, and which he would support.

Mr. John Aird, M.P., expressed his acknowledgments to Mr. Fraser, the Company's Engineer, for the generous manner in which he had always come to the front to assist the firm in the various difficulties they encountered in carrying out their contract. He also testified to the good conduct of the workmen; and expressed the obligations of the firm to those ladies who had interested themselves in the well-being of the large staff of men employed on the works.

The Chairman, in responding to the toast of his health, spoke in high terms of their Engineer, Mr. Fraser, and alluded to the long period of time—57 years—during which their excellent Secretary, Mr. Coe, had ably filled his important post. Mention was also made of Mr. Basil P. Ellis, who, as connected with Mr. Aird, had taken an active part in the supervision of the works of which they had seen the consummation that day.

The proceedings then terminated.

The funeral of the late Mr. J. O. N. Rutter, whose death, at a very advanced age, was notified in the *JOURNAL* last week, took place on Wednesday last, at the Extra-Mural Cemetery, Brighton. The *cortege*, consisting of an open car and five carriages, left the residence of the deceased, at Black Rock, at noon, arriving at the cemetery gates at one o'clock. There it was met by the Engineer and Manager of the Brighton and Hove Gas Company (Mr. J. Cash, Assoc. M. Inst. C.E.) and several of the Directors, officers, and employees of the Company. The coffin was carried from the chapel to the grave by six of the men from the Black Rock works. It bore this inscription:—"John Obadiah Newell Rutter; born 19th April, 1799; died 27th July, 1888."

MR. BRAY'S ATTACKS UPON MEMBERS OF THE GAS INSTITUTE.

In another column will be found an abstract report of the discussion in the Salford Town Council last Wednesday on the motion of Mr. Mandley with reference to Mr. Bray's attack upon The Gas Institute in his last pamphlet. As a further indication of the spirit in which Mr. Bray is acting—no longer with regard to those members of the executive of the Institute who were identified with the management of the Gas Section of the Crystal Palace Electric and Gas Exhibition, but with reference to gentlemen who had nothing to do with that undertaking, the following reprint of two letters addressed by him to the Editor of the *Rochdale Observer* may be read with advantage. It will be remembered that a comment appeared in the *JOURNAL* for June 12 upon the attack made by Mr. Bray upon Mr. T. Banbury Ball, the Engineer of the Rochdale Corporation Gas-Works, merely because he happened to be a member of the Council of The Gas Institute, and which might have had some connection with the refusal of the Town Council to advance Mr. Ball's salary by more than £50 per annum, instead of £100 as recommended by the Gas Committee. It is to these and subsequent transactions of the Town Council that Mr. Bray's letters refer. It will be noticed that the second is dated subsequently to the legal proceedings which resulted in Mr. Bray's retention as a member of the Institute:—

THE PAMPHLET ON "CORRUPT PRACTICES IN THE GAS INDUSTRY."

To the Editor of the "*Rochdale Observer*."

Sir,—Referring to your issue of the 9th inst., containing report of Town Council meeting in which the above pamphlet, issued by me, was referred to, I beg to say that I have addressed a letter on the subject to His Worship the Mayor of Rochdale, of which I enclose you copy, and which I shall be glad if you will insert in your next issue.—I am, yours truly,

Blackman Lane, Leeds.

GEO. BRAY.

To His Worship the Mayor of Rochdale, Mr. Councillor Petrie.

Dear Sir,—On my return from London I find a copy of the *Rochdale Observer* containing a report of the meeting of the Rochdale Town Council in which my pamphlet on "Corrupt Practices in the Gas Industry" was freely mentioned. I am glad to find from that report that several councillors took the view that inquiry should be made in Rochdale, and that, pending such inquiry, judgment should be reserved. But I regret to find that your Worship, instead of awaiting the result of any inquiry, is reported to have said that my "pamphlet had been supplied to the Council at a critical time, and it had a suspicious appearance. The person who had printed it had not had the courage to put his name to it." The insinuations in the above quotation are not fair, as I will show; consequently, I submit, ought not to have been made by your Worship.

First as to the pamphlet being "supplied to the Council at a critical time." I was absolutely ignorant of the fact that there was going to be a Council meeting at Rochdale, or that Mr. Ball's salary was about to be discussed, otherwise the pamphlet would have been kept back for a day, so far as Rochdale was concerned. The pamphlet was sent to Rochdale at the same time that it was sent to the other corporations and gas directorates of the country whose officials were members of the Council of The Gas Institute.

Then as to your statements "that the pamphlet had a suspicious appearance, and that the person who had printed it had not had the courage to put his name to it," I will only say that I could not have published the pamphlet more openly than I did. It bears my name and address in prominent characters; and, that being so, it was not necessary, either according to law or practice, to allow a printer the advantage of advertising his name. I therefore respectfully submit, Sir, that by the reflection just quoted you supply another severe example to those contained in the 13th, 14th, and 15th pages of my pamphlet of the difficulties and dangers those have to encounter who attempt to expose malpractices in the gas industry.

Hitherto I have appealed in vain to the Council of The Gas Institute for an inquiry into alleged malpractices, and for having made charges against some of The Gas Institute officials I have been expelled, without inquiry, from the Institute, at the instance of the Council of which your Corporation Gas Engineer, Mr. T. Banbury Ball, is a member. As the gas engineers and managers derive the power mainly from the official positions they occupy, I have now determined to appeal to the public bodies by whom those gentlemen are employed; and if these bodies decline to assist in purifying the gas industry, they need not be surprised if honest trading has to retire into oblivion.

As your observations appeared in the *Rochdale Observer*, I am sending a copy of this letter to that paper.—I am, dear Sir, yours faithfully,

June 22, 1888.

GEO. BRAY.

MR. BALL, MR. BRAY, AND THE GAS INSTITUTE.

To the Editor of the "*Rochdale Observer*."

Sir,—I read in your issue of the 7th inst. the report of the second discussion in the Rochdale Town Council upon the Corporation Gas Engineer, Mr. Ball, The Gas Institute, and myself; and I shall be obliged if you will allow me to make some observations thereon. I should have asked this favour last week, but I deemed it desirable not to enter into any further public controversy on this business pending the decision of the Court of Chancery in the action which I brought against the Council of the Institute, and which was heard before Mr. Justice Kay on Friday last. As you may be aware, the Council put in no defence. They admitted that my pretended expulsion from The Gas Institute was illegal, volunteered to reinstate me, agreed that the hearing should be taken as the trial of the action, and submitted to a perpetual injunction with costs.

It appears that since the Town Council meeting in June, the Gas Committee had called upon Mr. Ball to explain, and that the Committee had passed a resolution that they "are perfectly satisfied with the explanation of Mr. Ball." A peculiar feature of this investigation is that I was not asked to be present, and that only Mr. Ball was called upon. What Mr. Ball said, I therefore cannot say; but if the speech made by Alderman Petrie, the Chairman of the Gas Committee, and reprinted in your columns, contains substantially Mr. Ball's explanation, then Mr. Ball has deceived the Committee.

According to Mr. Alderman Petrie, my complaints against the officials of The Gas Institute are entirely based upon the way in which the jurors at the Crystal Palace Exhibition performed their functions; whereas that feature is but a small fraction of the case. Some of my charges, upon

which Mr. Ball has apparently ventured to give no explanation, are these:—

That the Gas Section of the Crystal Palace Exhibition was not a *bona fide* project; and that it was launched under false pretences by officials of the Institute.

That a sum of over £6000 was obtained by false pretences from corporations and gas companies for the support of the Gas Section.

That grave malpractices took place in the management of the Gas Section.

That a fraudulent official report of the Gas Section has been published.

That the Council of The Gas Institute are, as an organized body, defending certain of its officials who have perpetrated these grave malpractices.

These charges affect the whole morals of the Council and of the Institute; and I submit that the conduct of any official who seeks to prevent these charges being investigated, or to expel the member who makes the charges (and who declines to withdraw them without investigation), is open to the gravest suspicion.

My charge against Mr. Ball is that he has been a member of the Council of the Institute during the past three years, and that as such, so far as I am aware, he neither spoke, wrote, nor voted in favour of inquiry into my charges of corruption, nor against my expulsion from the Institute for adhering to them. That being so, the Corporation and the ratepayers of Rochdale, as well as myself, have a right to know whether Mr. Ball's motive was to discourage corruption or to discourage the exposure of corruption. He must be judged by his action.

The Gas Committee's resolution of "perfect satisfaction with the explanation of Mr. Ball" carries with it, in my opinion, no weight, removes from him no onus, and is a direct blow to honest trading.

The necessity for caution in passing resolutions of "perfect satisfaction," and the possible smallness of their value, are strikingly illustrated by the fact that on the day following the passing of the resolution of perfect satisfaction with Mr. Ball's *ex parte* statements, a former Rochdale Gas Manager—Samuel Hunter—was sentenced to five years' penal servitude. When that gentleman was at Rochdale, charges of malpractices were brought against him; and the Gas Committee whitewashed him, after an examination with closed doors, by a vote of entire confidence. This motion has been recently referred to by Mr. J. C. Mandley in the *Manchester Guardian*.

Then in the case of the Metropolitan Board of Works, the Chairman—Lord Magheramorne—said on Tuesday last, regarding one of the tribe of officials convicted of corruption: "As to Mr. Goddard, I was never more surprised in my life than when I was informed as to what had transpired in respect to him. I could scarcely believe my ears." Just so, and all the guilty officials were whitewashed by the Board a short time since, and their accusers condemned.

The impropriety of whitewashing without proper enquiry might be illustrated *ad infinitum*.

For years persistent efforts have been made to prevent inquiry into my charges of malpractices against certain officials of The Gas Institute, and during the past twelve months the Council of The Gas Institute, of which Mr. Ball was then a member, has sought, by practices that may properly be termed infamous, to obtain my expulsion for persisting in making those charges. How much the accused feared exposure may be gathered from the recital of the proceedings in the first paragraph of this letter.

If the Rochdale Gas Committee wish to aid in purging the Council of The Gas Institute of its corruption, let them make a proper inquiry into my allegations affecting Mr. Ball's conduct. If they are true, let them censure him; if they are not true, let them censure me.

In conclusion, permit me to say that, whatever the Rochdale Gas Committee may or may not do, it is my intention to make every member of the Council of The Gas Institute concerned in the recent infamous attempts to secure my expulsion from the Institute personally responsible for his share in the transaction.—Yours truly,

Leeds, July 19, 1888.

GEO. BRAY.

Notes.

IGNITING GASEOUS MIXTURES BY INCANDESCENT LAMPS.

A series of experiments to determine the degree of danger to be apprehended from the breakage of incandescent electric lamp globes in explosive atmospheres, has been conducted by Lieutenant H. Hutchins, of the United States Navy. A mixture of oxygen and hydrogen was fired by a purposely broken Swan lamp; but a mixture of one volume of marsh gas to seven-and-a-half volumes of air was not exploded by similar means. When a lamp was broken in an atmosphere of coal gas, the filament continued to burn; the gas being probably decomposed and carbon deposited on the filament in a manner similar to that in the "flashing test" in the manufacture of incandescent lamps. In another experiment a mixture of one volume of coal gas to six volumes of air was used, and a lamp glass was broken in it; the result being a fairly violent explosion. As a result of these experiments it is concluded that the filament of an incandescent electric lamp, if it comes into contact with either a highly explosive gas, such as a mixture of oxygen and hydrogen, or a comparatively weak explosive mixture, such as coal gas and air, will ignite them. If the lamp filaments were so frail as to be always broken by the first inrush of gas these lamps might be safer; but unless this fact can be more clearly established, it appears that ordinary incandescent lamps must be classed as a dangerous means of lighting in an explosive atmosphere, because ignition of the surrounding gas would follow upon an accidental breakage of the glass.

THE ORIGIN AND UTILITY OF ELECTRIC WELDING.

It is stated in a lecture by Mr. O. K. Stewart, recently delivered before the Boston Electric Club, that the phenomenon of electric welding, which is now shown at the Glasgow Exhibition, was accidentally discovered about 11 years ago by Professor Elihu Thomson, who then held the Chair of Chemistry and Applied Mechanics at the Philadelphia Central High School. Professor Thomson was delivering a course of lectures before the Franklin Institute; and, among other experiments, he reversed an ordinary induction coil, and while so doing he brought the terminals of the coarse secondary winding of the coil into mutual contact, and was

surprised to observe that a high temperature was developed instantaneously at the point of contact—so high, in fact, that the ends of the wire melted and stuck together. Professor Thomson was, however, fully occupied for the next five or six years in teaching and lecturing, and perfecting the Thomson-Houston system of electric lighting; and it was not until he perceived the necessity, in the regular way of manufacturing electrical apparatus, for some means of jointing copper wire more perfectly than was possible by known methods, that his mind reverted to his old lecture experiment and the possibilities which it indicated. Copper wires were electrically welded long before the process was applied to any other purpose. It is now used for all kinds of welding, large and small, on account of its quickness, efficiency, and the avoidance of all risk of burning the metal or introducing impurities into it, as in the old method of welding iron. It is expected that boiler tubes and all kinds of metal tubes can be treated in the same way, including lead and composition pipes. The old-established "wiped" or plumber's joint will thus be superseded, as well as blow-pipe joints and burnt joints in lead work. The advantages of electric welding have been summed up as follows by Mr. Stewart:—Absolutely pure heat, with absolutely perfect means of regulation, with the heating constantly before the eyes of the operator, with a neatness to which ordinary methods cannot at all be compared, with an increased economy of (in all ordinary cases) at least 300 per cent., and with absolute safety of apparatus.

A VALVELESS PUMP.

A new form of valveless pump construction, calculated to do good service in pumping thick and dirty fluids, is described in the *Génie Civil* as having been invented by M. Monrichard, an inspector of forests at Montmedy. The pump consists of a horizontal cylinder, which is traversed longitudinally by a piston-rod capable of a reciprocating motion through stuffing-boxes at each end of the cylinder. Upon this rod is fixed a helicoidal piston, which forms as it were one complete turn of a screw-thread upon the rod. Two rollers project inside the cylinder, and engage with the screw-piston. The action of the pump is now obvious. The piston-rod is long enough, after passing through the cylinder, to carry a fly-wheel at one end and a crank-handle or pulley at the other. Rotary motion being given to the piston-rod (by hand or power), a reciprocating motion must also follow, which causes a suction and expulsion on the two sides of the piston, and consequently draws and expels fluid through suitable inlet and outlet pipes. The resultant of the two combined rotary and reciprocating motions is a curve bordering upon an ellipse. The pump acts in either direction, according as the wheel which drives the piston-rod is turned. Consequently, when mounted on a travelling tank, it can be made to fill or empty the vessel at will. The larger sizes of these pumps are provided with air chambers. Fluids charged with solid substances are easily pumped by these machines. The peculiar form of the piston has the effect of bringing all solid bodies into the current of the fluid, and these generally pass through the pump intact, although, in case of a jam, the working parts are strong enough to crush any ordinary floating bodies.

AN IMPROVED WATER FILTER.

A committee of the Franklin Institute have reported favourably on the Hyatt system of water filtration. The designer of this system proceeds upon the fact that simple filtration is not competent to arrest the extremely fine muddy silt held in suspension by some waters; and that some means of aggregating the impurity is called for before it can be removed. The Hyatt filter is simply a body of ordinary sand supported on a perforated false bottom, the whole being enclosed in a wrought-iron cylindrical vessel. A small portion of the muddy water to be treated—not more than a fraction of one per cent. of the total volume—goes through a compartment of the filter in which are contained lumps of alum. A minute proportion of alum is thus dissolved, and passes into the filter, where it is mixed with the main body of water; the quantity of alum used being less than one grain per gallon of water. The suspended clay and other earthy matter, which is of a basic nature, has the property of precipitating the alumina of the alum, causing it to separate all through the water in the form of gelatinous flocks. These minute particles bring together or coagulate the finely suspended matter, converting it into such a form that the filter will easily and completely remove it. The supply of water to this coagulation is governed by a valve regulated by a scale, every degree of which corresponds to the solution of a certain quantity of alum. In consequence of this arrangement, whereby the solution of alum is restricted to the quantity necessary to deal with the water to be treated, the minute amount of alum employed is entirely absorbed in doing the required work, and is afterwards removed from the solution. In this way the fine silt which could not otherwise be removed by filtration is converted into such a form as to be easily removable, and the resulting filtered water is perfectly bright and clear, no matter how dirty or muddy it may have been previously. The filter is easily cleaned by a reversal of the current of water; and it works with great freedom and rapidity when compared with filters in which the operation depends upon the closeness of the particles of the filter bed.

MR. NORMAN T. GRAY, nephew and pupil of Mr. J. W. Gray, Engineer of the Birmingham Corporation Water-Works, has been appointed by Messrs. Chamberlain and Hookham as Engineer of the central electric lighting station which they are establishing in Birmingham.

Communicated Article.

MANAGEMENT OF GAS-WORKS EMPLOYEES.

FIRST ARTICLE.

Except in the very smallest gas-works, the manager is not able to carry on the various operations without assistance; and in large works he becomes an employer of labour to a very respectable extent. But in approaching the labour question, it is well to remember, that for all practical purposes, we may regard the gas-works manager as really carrying on all the operations himself. He has not time, nor it is not worth while for him, to expend his energy in charging the retorts, keeping furnaces in order, and other manual labour; and therefore he employs qualified men to do the work in his place. The same in the purifying-house, in regard to the mains and services, and all the other departments incidental to the manufacture, purification, and supply of gas. On the large scale, each of these branches assumes sufficient importance to be placed in charge of a responsible and well-qualified superintendent; and so there is a further sub-division of labour. And some gas undertakings comprise several distinct stations or works, each placed in charge, perhaps, of a resident engineer. Still, whatever the circumstances, there is one person who is responsible for the whole; and although his assistants at the head of various departments may take a great deal of the detail off his hands, to a great extent it is necessary that every detail should be as clearly before his mind as if he was actually engaged in the performance of the same.

An important part of the duties of the manager of any gas undertaking of respectable size, then, is the engaging of thoroughly trustworthy and competent subordinates. Two things are necessary to this end. Suitable candidates must be within reach, and the manager must have sufficient discernment to recognize them when they offer themselves. Considerable experience and judgment are necessary in order to put the right man in the right place in each case; and the frequently-used phrase "management of men" carries a great deal more meaning than appears at first sight, and has more to do with the comfortable and satisfactory progress of operations than many would be inclined to believe. Experienced gas engineers are sometimes heard to complain because a board of directors or a corporation committee seem to suppose that any intelligent artisan can manage a gas-works; yet they not unfrequently exhibit a failing of a similar character, in putting any respectable person on who offers himself, as retort-house foreman or in other responsible position. Fortunately, in this country there is usually no difficulty in meeting with men well fitted to fill each and every vacancy; but this state of things does not extend to foreign parts. Sometimes considerable difficulty arises in these circumstances in making the best of the unsatisfactory material at disposal, and it may be necessary to send to the home country for suitable men.

It is well to bear in mind that, when once a man is appointed to a post with a prospect of permanent employment, he establishes a sort of vested interest in that post, rendering it difficult to take him from it, although it may be advisable to do so; and this increases with the period of time during which he has held the office. If he is a drunkard, or given to other bad habits which interfere with the proper fulfilment of his duties to the best of his ability, there is at once a tangible reason for discharging him. But he may be highly respectable in private character—for the student of human nature will find as much to respect and to admire in characters exhibited amongst the working classes, as amongst those moving in higher grades of society—and yet be utterly unsuited, in respect to natural ability, for the position to which he is appointed. Under these circumstances, the manager cannot remove him without incurring certain opprobrium. The reason for the change is not obvious to his fellows; and therefore the dismissal is said to be due to prejudice or other unworthy motive. A man of clumsy, slow, and awkward movements will never make a good retort-house hand; yet if he has been engaged as such for some years, and his mates have become used to him, his removal in favour of a candidate physically more suited for the work would be regarded as nothing else than an injustice. Some men will work with the shovel for years and yet never learn to use it properly. Even in such a simple operation as throwing up a load of coke, it will be observed that one man can do it in half the time, and apparently with the expenditure of less than one-half the labour, that is required by another to do the same work. One of the greatest difficulties in connection with taking over works that have been neglected or badly managed, is that of dealing with the men, who may not only have got into slovenly or idle habits, but in many cases are utterly unsuited for the positions they hold. The only real way of finding out whether a man is really qualified and fitted for any responsible post—such as retort-house foreman, captain of a gang, purifier-house foreman, &c.—is to let him try it for a time. In appointing a man to such a position, it is well, therefore, to let him begin *pro tem.*, on the understanding that he will not be permanently appointed unless he proves to be in every way equal to the post. The same principle may be advantageously applied in almost any case. One benefit gained by it is that the new-comer exerts himself to acquire the details of his duties; and becomes more competent than he would otherwise be after holding his post for half a lifetime.

But few of those who read these remarks are likely to be called upon to commence a gas-works *de novo*; the probability is that they will find the works already in operation, and that their pre-

decessors have carried them on with some degree of success. It is a great mistake to find fault with everything that has previously been done, or to set to work making sweeping changes before all the special circumstances of the undertaking have been thoroughly mastered; for to have to fall back again on the old plan, as being the best after all, is rather humiliating, and indeed a confession of failure. The first thing is to get thoroughly acquainted with the way in which operations have been carried on. If any abuses exist, such as the employment of incompetent men, or if any improvement or economy in working can be introduced, the matter can be plainly set before the workmen, who are usually amenable to reason, and their co-operation in the matter may be sought. They will apparently be quite willing to fall in with any new plans that offer prospect of improvement; yet the British workman possesses some degree of stubbornness and prejudice in favour of old customs and ways of working, which can only be overcome by watchfulness and determination.

It is only after everything else fails that the alternative of discharging a man should be resorted to—except, of course, in cases of offences against duty or discipline so grave as to call for summary punishment. There are times when it is necessary to be severe; but if this course is taken on the heat of the moment and in the absence of a really justifiable cause, public sympathy goes with the man, and a certain loss of influence is the result. The manager must make it clear that he is the master; but as a rule the men at once accept him as such—provided he shows himself competent to fill the position, and discharges all his duties in connection with them in a manner worthy of their respect. As such his course of action will be plain and clear. It should admit of those who carry out their duties faithfully, feeling secure and sure of receiving just treatment; but at the same time everyone who neglects his work should have a notion of what he has to expect as the result of such neglect. There is also much difference between ignorance or error of judgment, and intentional laziness or negligence, and this the employer of labour must be quick to appreciate.

These suggestions are not laid down as a guide that should be rigidly followed in dealing with workmen. As a matter of fact everybody has his own way of arranging these matters, which indeed are scarcely of a nature to admit of formulation in writing, and can only be acquired by experience. Still, a few remarks on the subject may not be altogether useless or devoid of interest. There should be a high standard for each *employé*. None, even the ordinary labourers, should be jeered at as "drunken rascals" if they take a drop too much at holiday time; nor should they be contemptuously termed "stupid" or "blockheads" if they fail to carry out their duties properly. Such a course only has the effect of driving them into a sullen, "don't care" sort of way of scamping through their duties, in a manner that seems to offer least trouble to themselves. They should rather be encouraged to set a high value on their work. Even the lowest of all should be made to feel that he is of some consequence in relation to the carrying on of the whole concern, that he is looked upon as being quite able to fulfil the allotted task comprised in his narrow and apparently insignificant field of labour, and moreover is expected to execute it heartily.

(To be continued.)

We understand that Mr. B. A. Lewis, who was formerly assistant to Mr. T. H. Martin, Assoc. M. Inst. C.E., at Barnet, and subsequently went to Wantage, has been appointed Assistant-Manager of the Cape Town Gas-Works, under Mr. A. Wilson, and will shortly leave England for the Cape.

An American physician—Dr. Donald C. Hood—has collected many facts relating to the use of salicylic acid for rheumatism. Of 728 patients treated with salicylates, 523 were relieved of their pains within seven days; whereas of 612 patients treated by other methods, only 140 were relieved within the same time.

We learn that Mr. F. G. Dexter, who has occupied a position on the gas engineering staff of the Great Western Railway Company, has been appointed Manager of the Wantage Improvement Commissioners' Gas-Works (for which post applications were invited by advertisement in the JOURNAL a fortnight since); and he will enter upon his duties to-day. It may be mentioned that Mr. Dexter took the first prize medal in both the Ordinary and Honours Grades of the City and Guilds of London Institute Examinations in "Gas Manufacture" in two consecutive years; and has obtained first-class honours, with second prize (£5 and a bronze medal) from the same Institute in the "Fuel" subject. Besides these, he is the holder of first-class certificates in some half-dozen cognate sciences. This book-learning undoubtedly told well in his favour; but without his eight years' practical experience and his testimonials, it, of course, would not have secured him the appointment. At the same time, his success is a testimony to the value of the City and Guilds Institute's Technological Examinations, and especially of those on "Gas Manufacture," to which reference was made in our editorial columns only last week. If this notification of what many may regard as a comparatively insignificant appointment has received rather more than the customary attention at our hands, it is with the view of stimulating and encouraging those who are entering the gas engineering profession to avail themselves of the opportunities placed in their way to make themselves thoroughly proficient members of it. It may be mentioned that there were about 70 applications for the Wantage appointment.

Technical Record.

NORTH BRITISH ASSOCIATION OF GAS MANAGERS.

THE ANNUAL MEETING IN GLASGOW.

In the JOURNAL last week we gave the general report of the proceedings at the above meeting, together with the Inaugural Address of the President (Mr. David Terrace, of Dawsholm) and the paper read by Mr. G. R. Hislop, of Paisley, on "Gas-Burners for Photometrical Purposes." To-day we continue the publication of the papers; reserving the discussions thereon until the Official Report has been passed by the Revision Committee of the Association.

A YEAR'S EXPERIENCE IN THE MANUFACTURE OF SULPHATE OF AMMONIA.

By ROBERT COWIE, of Tillicoultry.

About two years ago, the Company with which I am connected decided to work up their ammoniacal liquor into sulphate of ammonia. They had from time to time received offers to take the tar and liquor for a year or term of years; but the amount offered was so small that they concluded it would be preferable to manufacture sulphate instead of selling the liquor. After having made a few experiments, it was decided to erect plant for the manufacture of sulphate; but before beginning its erection, I paid a visit to three gas-works where sulphate is made, to inspect the plant in use. I was well received by the managers; and all my questions were readily answered. The difference between their works and mine was very great indeed. Still, the information I obtained was very useful; and to these gentlemen I tender my warmest thanks. Here let me say that a remark which was made at the meeting of the Association held in Edinburgh in 1886, in the discussion on Mr. Dempster's paper,* made me think there was an immense amount of worry and anxiety connected with the manufacture of these residuals. I thought I had quite enough of this without any more. However, the decree had gone forth, and I was determined to face it.

By this time the season was getting advanced; so, with as little delay as possible, buildings and plant were erected. I must say that for nearly six months I had plenty of worry and anxiety; many little things occurring which I did not foresee, and which were troublesome. The chief cause of trouble was not having a proper saturator, and working with acid made from pyrites instead of sulphur acid. By using acid made from pyrites I could not get a white salt; and a great deal of skimming was necessary. Besides this, the condenser and purifier were too small.

The first thing to give way was the saturator, which was cast all in one piece, but was not of pure chemical lead, and consequently did not stand the acid for more than a month's working, when it was perfectly riddled with small holes. After this I had to work away as best I could with the box with which I had been experimenting, till a new one was made.

Let me here describe the plant I have been working with during the past twelve months. We procured a good second-hand steam-boiler (egg-ended), 20 feet long by 3 ft. 6 in. diameter, set in the usual manner. Placed near the boiler is the saturator—a wooden box lined with pure chemical lead, 15 lbs. to the foot, and all joints well burnt. Its dimensions are 4 feet long by 3 feet wide, with partitions running from side to side; the bottom of the saturator having an inclination, to allow the salt to be fished out during the operation. The saturator is connected to the boiler with a 12-inch wrought-iron tube, with stopcock and flange 2 feet from the top of the saturator, where it is bolted to the flange of the lead pipe which goes to the bottom of the saturator, along its whole length, and is perforated with a number of holes to allow the ammonia free exit into the acid contained in the saturator. Alongside the saturator is a wooden box, 3 feet long by 2 feet wide by 1 ft. 8 in. deep, lined with lead 4 lbs. to the foot. On the top of this box is placed the drainer, also lined with lead of the same weight, having an inclination to allow all the moisture to run into the box below. A few feet from the saturator is the storehouse, the floor of which is laid with lead 4 lbs. to the foot; the walls being of lead to a height of 4 feet. Above this are boards overlapping each other to near the roof. The floor has a fall towards one end, at which is placed a lead box to catch all drippings from the wet sulphate; also a false bottom of wood to preserve the lead from injury by shovels.

The operation of making the sulphate is as follows:—The liquor is pumped into a tank, 12 feet long by 4 feet square, above the boiler at one end, and allowed to settle. About 900 gallons are run into the boiler, and a fire is started under it. In about two hours ammonia begins to come over into the saturator, which is half filled with acid. The ammonia is arrested by the acid and formed into sulphate, which is fished out, and acid added as required; while the carbonic acid and sulphuretted hydrogen pass up a pipe at the other end of the saturator into the condenser, which is composed of a series of 4-inch pipes outside, on the wall of building. The last pipe is placed inside one much larger, through which runs a constant stream of cold water, which cools the waste gases before they pass to the purifier, which is much smaller than it would have been if I had had more space. It is only 3 ft. 6 in. long by 3 feet wide and 3 feet deep, and has two trays, which are covered with oxide of iron. The gas enters at the bottom, and passes up through the oxide. At the top of one of the

sides is a 5-inch pipe connected with the flues of the boiler. When the lid of the purifier is on, the gas passes through this pipe, round the flues, and up the chimney. There is no disagreeable odour whatever during the operation. I may here mention that if the fire under the boiler becomes too strong, causing the saturator to throw off the gases very rapidly, we have a good deal of steam. This I intend to remedy by increasing the condensing power. It takes about 12 hours to distil a charge. I have not as yet used lime or soda to liberate any fixed ammonia, but intend doing so this year. When the charge is finished, the waste liquor is run off, and the boiler refilled on cooling. Should there be excess of mother liquor in the saturator, I have a coil of lead pipe round the bottom, in front of the partition, through which steam is blown, and the liquor evaporated. After cooling, the excess of salt crystallizes, and is fished out before beginning again.

With the plant I have just described, I may say I have had no trouble or worry. The men know now all that is required to be done. I have not employed any additional hands to look after it; so that no extra wages have been incurred. During our heaviest make, the apparatus is at work once, and sometimes twice every week, as we are fairly well off for storage room for tar and liquor, including the boiler, which is no sooner emptied than it is filled again. Thus our sulphate making does not interfere very much with our ordinary work during the busy season.

From the 836 tons of cannel coal carbonized last year, I obtained 8 tons 17 cwt. of sulphate, or upwards of 23 lbs. per ton of coal. The following statement shows the result of our working:—

Sulphate sold, 8 tons 14 cwt.	£101 9 7
Do. in stock, 3 cwt., at 12s.	1 16 0
	£103 5 7
9 tons of acid.	£32 10 0
5 cwt. of coke, at 6s. 6d.	1 12 6
10 p.c. on capital (£100)	10 0 0
	44 2 6

Leaving a surplus balance of. £59 3 1

The sulphate was all disposed of in the district—I had no trouble with it. The farmers who bought it brought their carts and bags with them to take it away. I sold as much as 3 tons 6 cwt. to one farmer; to another, 1 ton 8 cwt.; to another, 1 ton; and to others, quantities as small as 1 lb., 3 lbs., and 7 lbs., to be used for flowers and vegetables. Some of the farmers to whom I sold sulphate last year told me they were pleased with the results; and they have taken more than double this year.

The plant I have described is equal to the requirements of a much larger works than the one of which I have charge. It is not very costly; and it works well. I am aware that there is the continuous process by various makers; which no doubt would be preferred in large works, as perhaps better results are obtained. My Directors are pleased with the past year's working. I hope, if possible, to make it more profitable; and I shall be pleased to receive any information that will help me to make it so.

COAL TAR AS FUEL FOR STEAM-BOILERS.

By JOHN M'CRAE, of Dundee.

About three years ago, when the sudden and serious fall took place in the value of the secondary products produced in gas-works, many gas managers—ever desirous of doing their very best for their employers—were forced to look around for some better market in which to dispose of the products which had so seriously fallen in value. This was no easy task; and even now it forms very uphill work indeed. A comparatively new market has been created for the disposal of boiled tar at several of the German ports; but the expense and difficulty of loading ships with tar in casks take very much from the saving derived from the new manner of disposal. It occurred to me, therefore, that we must look nearer home for a remedy.

In all gas-works of any magnitude, a considerable quantity of fuel must be employed for the purpose of supplying the works with steam for the exhausters-engines, chemical apparatus, thawing purposes, &c. Whether this fuel consists of coke or of coal will not in the least affect or alter my figures. I have no doubt if any manager discovers that he is working more economically by selling the coke and using a cheap small or other coal, he will adopt the cheapest process. In Dundee, where we get a good price for coke, I found, for the purpose of steam fuel, it would be far cheaper to buy small coal costing from 5s. to 5s. 6d. per ton delivered in the works, and dispose of the coke. The question of fuel then lay between coal and tar; and I have experimented somewhat extensively to ascertain the true relative values of the two classes of fuel. For the purpose of this paper, and within the last few days, I made a further examination into the question; and the results arrived at will be those here quoted. The coal we employed was what is known as Stravenhouse small coal, which costs 5s. per ton delivered. The experiment in each case lasted 48 hours. The tar employed was what is known as boiled tar; the naphtha having been previously removed, but the pitch oil left in the tar. The value of this tar in Dundee is about 4s. per ton. The following are the figures:—

Coal, 10 tons 16 cwt., at 5s.	£2 14 0
Tar, 1460 gallons (or 9 tons. 3 cwt., 160 gallons = 1 ton), at 4s.	1 16 7

Saving per day by using tar £0 17 5

And this at the longest day, when we are using a mere fraction of steam, as compared with our winter requirements, and consequently

* See JOURNAL, Vol. XLVIII., p. 331.

the profit is proportionally less than it will be when we are in full work.

And now allow me to direct your attention for a short time to the appliance made use of in accomplishing this tar-burning. On the wall is shown a diagram giving in detail the injector known as C. and W. Walker's patent tar-sprayer burner; and it is supplied only by that firm. The tar, which has been brought forward to the boilers in a thoroughly liquid state, is discharged from the

centre of the injector into the furnace of the boiler. Surrounding the centre nozzle of the injector is an annular space through which high-pressure steam passes, also into the furnace. The meaning of this steam moving along with the tar is to force a draught, as well as to raise the temperature of the tar, and so partially convert the tar into vapour; thereby making the combustion more complete. The flow of the tar is regulated by the very delicate sluices attached to the injectors. These valves consist of elongated cones and plugs, and are constructed not only for the purpose of regulating the flow of tar, but also for removing any obstruction or incrustation which may accumulate in the nozzle. In order to keep the tar in a liquid state (which in the winter time is not an easy matter), a small steam-pipe is passed through the centre of the tar-pipe; but, of course, no steam is discharged among the tar, as the presence of water in the injector prevents its correct working. The steam-pipe is simply passed through the tar-pipe, and a steam-trap attached to its end. In changing from the coal or coke fuel to the tar, little or no difficulty is experienced, and very rarely is a shovelful of any kind of solid material required. The furnace-bars have only to be kept covered to prevent the waste of tar and the too-rapid ingress of air; and when the furnaces are in full work, and being well and carefully attended to, the tar will be found to have been nearly all consumed before reaching the solid material covering the bars. The action is very much the same as in the paraffin-oil lamp. The wick is the medium by which the oil is brought to the point of combustion, where it is developed into light; but the wick remains little injured, although in close proximity to such intense heat. The oil burns, not the wick. In the tar-furnace, the tar itself burns, and the tar only.

It will be easily understood that a little experience is necessary to enable the attendant to fully understand the quantity of tar by which complete combustion is to be obtained, and which in no case must be exceeded. The moment one atom of tar is sent into the furnace beyond that which can be thoroughly consumed, you have then the most hideous discharge of black smoke (carbon) which it is difficult to describe, but which can be easily understood, and, I believe, can be seen within a few miles of where we now sit. I should mention that the injectors are fitted on the furnace doors; but the connections are of such a nature that the doors can be opened without disturbing any of the permanent fittings.

And now I have told you that the results detailed in this short paper were those obtained in the Dundee Gas-Works. This is so; but were I to leave the matter here it might be inferred that I considered similar results might be obtained in any and every gas-works. I would not mislead you; and therefore must detain you for a few moments longer in order to show you how my town is different from many others. Dundee is very peculiarly situated in this respect. It is a long distance from any

tar distiller's works capable of dealing with the large quantity of tar we have for sale during the winter. A large portion of the value of our tar must, therefore, go to the railway company, to cover the cost of transit between the two points, and so the tar distiller can allow us but a small figure for it at the starting-point. Then again, Dundee being far distant from the coal-fields, the coal is exceptionally high in price. I quite believe that in many of the west-country towns the coal for which we are paying 5s. per ton could be had for 3s.; and the tar for which we are receiving 4s. per ton, they would get not much under the double of this. Therefore, you see, in a place so circumstanced, the figures I have given would be most misleading. Still, I doubt not there are places as badly situated as Dundee; and it is to such places that my remarks are directed. I believe also that, in many towns distant from collieries, the tar might be sold to manufacturers for use in their steam-boilers; and such an arrangement would, I think, prove advantageous both to the seller and the user of this liquid fuel.

I think that as much has been said in regard to my subject as is necessary; but permit me to add that I believe there is a future for liquid fuels. I do not say tar, but more concentrated fuels, such as crude naphthas, paraffins, and pitch oil. When you see one of our large steamers taking coal into her bunker, it must have appeared to you that there was great waste of power here. Every ton of coal laid in must require a certain amount of power to carry it; and every ton of coal so laid in reduces the cargo-carrying power to this extent. A few gallons of oil will give you the steam-producing power of a ton of coal; and this is a fact which the owners of non-paying steamships should note. Take our locomotives also. Everything I have said in regard to steamships applies to them; and the comfort to the stokers, and the general reduction in labour would be very marked indeed. Of course, it may be argued that if there were such a large demand created for oils for furnaces, the old-fashioned law of supply and demand might come into play, and so force up the price of the article for which the increased demand had taken place. But I think this state of matters is rather remote, when we bear in mind the great oil-wells only now becoming developed, and the oils from which can be run in bulk direct from the wells into ships, and brought to this country at very low rates.

AUTOMATIC GAS LIGHTING.

By GEO. KEILLOR, of Nairn.

From the fact that the automatic system of gas lighting by means of an electric spark has been in practice for a few years and applied in many different ways, all with considerable success, and also from the fact that a considerable number of able papers have been read on the system at previous meetings of the Association, the subject is one which is well known, and one upon which it is difficult for me to add anything likely to be of more than passing interest.

At the outset, I wish to explain that it is not a lighter I have made, but an arrangement whereby these lighters can be used to much greater advantage than formerly. Before proceeding further I wish to emphasize the fact, in case of misunderstanding, that I have not come forward to read this short paper with the intention of making it appear that I can in the slightest degree improve these lighters so far as they are in themselves concerned. The Woodhouse and Rawson Company's Electric Lighter is a most complete instrument; and having had one in use during the whole of last winter, I can certify as to its unfailing accuracy in the lighting of public lamps, when fitted up in such a way as I am about to describe.

With your forbearance for a short time, I propose to describe a system of lamp lighting which I have had in practice during the past winter, whereby the pressure of gas by means of a governor combined with one of these electric lighters, operates as a complete automatic lighter; but before putting the model which you see before you in action, it may be interesting to the meeting if I were to give a short account of the circumstances under which I was led to make an experiment of the system under description, and the difficulties that I experienced in connection with the lighting of a pier-head lamp.

The pier at Nairn is about 200 yards long, and runs straight out into the Moray Firth. In 1884 the seafaring population of the town made application to the Police Commissioners for the erection of a lamp at the outer end of the pier, to serve the double purpose of helping the navigation of the Firth and lighting the entrance to the Harbour. In the following year the Commissioners, conscious of the necessity for the request, agreed to erect a lamp, and asked me for a probable estimate of the cost of extending the gas-main and furnishing and fitting-up a lamp. As requested, I submitted an estimate, at the same time informing them of the difficulties connected with carrying the gas-main along a pier, and the trouble likely to arise in lighting a lamp situated at a pier-head, owing to the sea being at times very stormy. However, I was entrusted to get the work carried out; and the lamp having been erected in October, 1885, was registered as a coast light. The light was all that could be desired; giving satisfaction to both the Commissioners and the seamen. All went well until the first storm, when, as I fully anticipated, my troubles in connection with the lighting of the lamp commenced. With the waves washing right over the structure, the lamp-lighter—I mean the animate lamp-lighter—dared not venture to the point of the pier to light the lamp; and yet it was just upon such a night as this that the lamp was most needed. To dispense with the necessity of going to the point of the pier

at all, I fitted up a burner with bye-pass, so as to burn at a low point all day; but, unfortunately, the jet of gas when lowered often got blown out during gusty weather. Another objection was raised to this system in respect of the waste entailed by the burning of gas during the daytime; and hence it was that I was induced to adopt the automatic system which I am now about to describe.

I purchased one of Woodhouse and Rawson's electric lighters with the necessary battery, &c.; and after experimenting with it at the gas-works, I contrived to combine the lighter with a governor constructed in the way shown in the model before you, which entirely obviated the necessity for laying a wire to the pier-head—a distance of about 500 yards. I need not comment on the difficulty which would be entailed by carrying a wire alongside a pier, further than to say that I was exceedingly pleased to get over the difficulty so easily. After affixing the wires to the governor in the permanent way shown in the model, I did not experience the slightest trouble; and as sure as the pressure at the gas-works is put on, so sure will all lamps fitted with this apparatus light up. The model, or rather the box and pillar shown is simply a rough-and-ready means of showing the apparatus combined; the battery and governor inside the box and the lighter on the top being actually the apparatus I had in use during the past winter. Now assume that I am at the present moment in the governor-house at the gas-works; the minimum or day pressure being (say) 10-10ths. The governor fitted inside the lamp-post is set at 12-10ths. Consequently it is down and the lamp out. Evening, however, comes on; and it is time to commence to load the station governor, so as to increase the pressure in the street mains for all purposes. We will accordingly now put on the first of the weights; and the moment the pressure reaches (say) 13-10ths in the street mains, all the lamps (unless the governor be loaded down to suit the time) fitted up on this system will immediately light up, as I will show by operating on the apparatus before you. Having now increased the pressure so as to raise the governor and connect the current—the lamps burning—we will suppose the pressure to be all on. Everything goes on as usual till the time for reducing the pressure; and if it is wished to extinguish any lamp (say) at 11 o'clock, or at any given hour, it is accomplished simply by loading the governor at the lamp so as to suit time and elevation. But this one being, we will suppose, a night-lamp, goes on burning till day-break; and seeing that the pressure has been reduced during the night and morning from the maximum to the minimum, the last of the weights will now be taken off; and you will observe that the moment the pressure is reduced to its minimum, the lamp will instantly go out and remain so till evening. Although the model before you only shows one lamp lighted up, I wish to explain that rows of lamps can be lit by means of one governor and battery, and that it matters not from what main the different lamps may get their supply; but there must be a lighter on each lamp, so as to convey the current, and turn the gas on and off. For a row of ten or more lamps, it is simply a matter of battery strength; and it makes no difference what the number of lamps may be, so far as the governor is concerned—it being there solely for the purpose of connecting the current.

I am confident that this is a system of gas lighting which will commend itself to all in charge of public lights. It is specially suitable for pier-head signal and night lamps as well as for town, steeple, and public building clocks—in fact, wherever gas is used. For town and steeple clocks, the system is exceedingly useful, and will entirely supersede the rather antiquated practice prevalent at the present time of setting the clock from time to time to turn up and down the gas according to the season of the year, and it also effects a saving of the gas burnt in these clocks during the daytime. In short, I am of opinion that there can scarcely be a more accurate system of automatic lighting than the one which I have shown. When night approaches, the pressure at the gas-works will be put on to suit the season of the year according as the day shortens or lengthens. Hence, by means of an apparatus fitted in connection with the gas supply of any public clock, building, or lamp, set to a certain pressure, the time of lighting and extinguishing would be wholly regulated by the man in charge of the station governor at the gas-works—thereby making the system completely automatic and thoroughly satisfactory.

Of course the electric lighter with battery can do all I have mentioned without the aid of a governor, if a push-button can be conveniently placed, and a wire carried to the required place, so as to perform by hand the duty which the governor does automatically; but in all cases such as I have described, and also in all outlying lamps, the governor which I have had the honour of bringing under your notice is, in my humble opinion, by far the preferable appliance. Of course, there are a great many other places where these electric lighters could be used, and where they would be exceedingly useful and economical; and it is surprising that they have not ere now come into more general use, especially where occasional lamps are required. I will briefly mention a few of the more likely places where they would be of very great service. They would be particularly so at railway stations, especially in smaller towns where there is generally a considerable lapse of time between the trains; and where a light is only required for a passing train. All outside lights could be lighted instantly, by the use of these lighters, a few minutes before the arrival of the train, and put out again the moment after its departure. Facilities for fixing up the lighters at railway stations are exceptional, as the batteries are at hand, and nothing further is required but the additional lighters and wires. In hotels and large dwelling-houses also, the system would be one of the greatest public convenience. In these establishments one sleeping in the top of the house may have occasion to go to the ground floor during the night, when on coming from his room, and by pushing a button placed at a convenient point, the staircase would be immediately lighted up, and when returning to his quarters, by pushing an adjoining button, darkness would again prevail. This system of the push-button will be found to be equally serviceable in flats of spinning mills, factories, and in show and sale rooms, doctors' surgeries, &c.

The cost of the combined automatic lighting appliance as you now see it is about £4 10s., including the cost of the governor. This governor, of course, I made to suit myself; but to light up a row of ten or more lamps which would necessitate a few extra cells to be added to the battery, and an additional lighter for each lamp, the total expense would be about 45s. per lamp. Extra cells cost 2s. 6d. each; and the best special wire about 6s. per 100 yards. The lighter and battery will last for a number of years; and all that the battery requires at any time is simply to be replenished with a little plain water added after the salammoniac, zinc, and carbon blocks.

I may here further state, for the benefit of anyone who may think of using a similar apparatus in the close vicinity of the sea, that damp from the salt water or even the sea air has a very injurious effect upon all metals and especially copper, which in a very short time gets quite green in colour, followed rapidly by verdigris; and, if not protected, corrodes the wire connections in a very short time. All wire connections should, therefore, be carefully covered up by whatever means may suggest itself. The means of protection which I adopted was to completely bury the battery in a sheet of common wadding, with a close case to cover the governor, above which I also placed a sheet of wadding.

THE MANAGEMENT OF THE BRISTOL GAS-WORKS.—We are pleased to learn that the Directors of the Bristol United Gas Company have appointed Mr. William Fiddes as their Engineer, in which capacity he will have control of all the Company's works, and will carry out such new works and extensions as the Directors may decide upon. We congratulate the Directors upon having taken the wise step of securing the services of Mr. Fiddes as their Engineer-in-Chief. He has had considerable practical experience in every detail of his profession, during the many years he has been assistant to his father (Mr. Walter Fiddes, M. Inst. C.E.), as well as an intimate acquaintance with the requirements of the city and districts. Besides his qualifications as an Engineer, Mr. William Fiddes is an able Chemist, proof of which is afforded by the valuable tables published in "King's Treatise on Coal Gas," showing the ultimate analyses of coals—analyses which were made by him while still serving his articles with the Company under his father. About the same time he was elected a Fellow of the Chemical Society, having previously distinguished himself as a National Medallist in the chemical examinations held under the Science and Art Department. The many friends and well-wishers of Mr. Walter Fiddes will be pleased to learn that his eldest son has received this important appointment in the Company with which his name has been so long associated.

THE LIGHT-GIVING POWER OF DIFFERENT GAS-BURNERS.

The occasion of the exhibition of illuminating appliances held in St. Petersburg under the auspices of the Russian Technical Society afforded an opportunity for conducting a series of tests on a large scale with different gas-burners. These tests were undertaken by Professor S. Lamansky, assisted by MM. E. Komaronski and J. Schelkownikoff; and full details, with the results of the experiments, are published in the report of the exhibition. Professor Lamansky has, however, republished the most important results in the *Journal für Gasbeleuchtung*; and, inasmuch as the different gas-burners were all examined by the same method, with the same gas, and by the same observers, it is possible to compare satisfactorily not only individual types, but also burners of different manufacture. We therefore lay these results before our readers.
